SCHOOLS OF OCCUPATIONAL THERAPY

At the 1933 Session of the House of Delegates of the American Medical Association a resolution was introduced that some plans be effected for the establishment of standards, ratings and inspections of training schools in occupational therapy. This program was referred to the Council on Medical Education and Hospitals, and all of the 13 existing schools were surveyed. The Essentials of an Acceptable School of Occupational Therapy were ratified by the House of Delegates of the American Medical Association at the Atlantic City Session in 1935, such standards to become effective on Jan. 1, 1939. A report of the Council on Medical Education and Hospitals to the House of Delegates in 1936 contained the names of 4 schools which had already met these standards. There are currently 7 schools on the approved list.

Occupational therapy is now accepted and used in the leading hospitals of this country as an established adjunct of medical treatment. The occupational therapist is trained to work under the direction of a physician and should be capable of planning and coordinating programs designed to recreate specific functions and to aid in the restoration of impaired functions. Additional uses of occupational therapy are found in the field of mental therapy and in the complete care of tuberculous patients.

Reports from the approved schools indicate that 146 students were graduated last year. Apparently 157 are expected to graduate during the calendar year of 1943. It is impossible at this time to estimate the needs for occupational therapists within any degree of certainty, but it is generally conceded that the demand will materially increase in the near future. For several years it has been reported that available positions in civilian hospitals exceed the number of graduates each year. With the increased use of occupational therapy

to assist in the restoration of functions in many of the injured personnel of the armed forces, it is thought that there will be a corresponding increase in the use of occupational therapy in civilian hospitals after the war.

Applications for approval of occupational therapy curriculums have recently been received from several additional educational institutions. If these courses are found to be acceptable, it is likely that the number of approved schools will be doubled within the next year. Senior students are already being trained in these schools or will be enrolled next year. This will greatly increase the annual number of occupational therapy graduates in the United States.

Prerequisites for enrollment in the approved schools vary considerably with the length of the training program. Five schools will admit students directly from high school, but the required course extends over a period of four or five years and includes all the prerequisites for admission to approved schools. Otherwise the minimum prerequisite is one year of college work, while the minimum length of training is twenty-seven months. Six of the schools grant a diploma when the student graduates, while 5 can offer a bachelor's degree in occupational therapy if proper courses are followed. Only 2 of the schools admit male students in their regular classes. The annual tuition varies from \$70 to \$400.

Correspondence regarding schools training occupational therapy technicians should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the American Occupational Therapy Association, 175 Fifth Avenue, New York City.

SCHOOLS FOR PHYSICAL THERAPY TECHNICIANS

The House of Delegates of the American Medical Association in 1934 requested that some plan be effected for the establishment of standards, ratings and inspections of schools for the training of physical therapy technicians. The Council on Medical Education and Hospitals assumed responsibility for this program and by 1936 had completed a survey of these schools. Certain minimum standards were formulated. These were presented to the House of Delegates of the American Medical Association and were ratified in May 1936. The first published list of 13 approved schools for physical therapy technicians appeared in THE JOURNAL in August 1936. At present there are 22 approved schools.

Emergency curriculums continue to offer intensive instruction in all the required subjects with only a minimum of experience in applying the various techniques. These courses are six months in length and involve approximately eight hundred hours of instruction in basic subjects and two hundred hours of practice. Following these courses the student is qualified to work under the direction of a recognized physical therapist in the Army. On completion of six months of supervised Army experience the student is eligible for graduation.

Recently the status of physical therapists in the Army has been defined by Congress, and they are given rank and grade similar to the nurses and dietitians. Nevertheless it is still possible to fill government positions

in the field of physical therapy through U S Civil Service appointments. Information on this subject can be obtained from any first or second class post office. In addition, positions are available in the women's corps of the armed forces such as the Waacs and the Waves.

It is understood that the Navy will need many physical therapists during the current year. Civilian hospital needs have not been met during the last few years, and after the war there will undoubtedly be greatly increased demands for physical therapists in both governmental and civilian hospitals.

Statistics for the calendar year of 1942 disclose that 352 students can be trained in the regular courses and 175 can be trained every six months in the emergency courses. A total of 426 students were graduated from the approved schools in 1942. One hundred and ninety-nine of these graduates were enrolled in the emergency courses.

During the last year there has been an increase in the number of schools that charge no tuition. This arrangement has been made possible in certain institutions which consider the time, effort and use of facilities in presenting these courses as part of their war contribution. In the schools which charge tuition the fees range from \$96 to \$435 for the regular course and from \$96 to \$420 for the emergency course. The mean tuition for either course is \$200.

* Courses are so arranged that any of the entrance requirements will qualify students for training: a = Graduation from accredited school of nursing; b = Graduation from accredited school of physical education; c = Two years of college with science courses; d = Three years of college with science courses; HS = High school graduation.
1 Male students are admitted.

2 High school graduates accepted for a four-year course leading to a B.S. degree; students admitted quarterly and tuition is \$147 per quarter.
3 Medical technology graduates with B.S. degree also admitted.
4 Nonresidents charged additional fee.
5 Those with degree from other colleges also accepted.

SCHOOLS FOR MEDICAL RECORD LIBRARIANS

Recently the American Association of Medical Record Librarians requested that the American Medical Association assume the responsibility of approving schools for medical record librarians. A resolution to this effect was presented to the House of Delegates of the American Medical Association at the 1942 session. This resolution has been acted on and the Council on Medical Education and Hospitals has been delegated the responsibility of establishing standards and of inspecting and publishing lists of approved schools. In an effort to fulfil this request, each of the schools previously approved by the American Asso-

ciation of Medical Record Librarians has been visited and minimum Essentials have been prepared. These standards will be presented to the House of Delegates of the American Medical Association at its next session. After official acceptance of the Essentials, the list of schools meeting the requirements can be published and new applications can be received. Graduate medical record librarians desiring registration should communicate with the Board of Registry of the American Association of Medical Record Librarians, St. Luke's Hospital, Milwaukee, Wis.

SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

The original survey of 196 schools for clinical laboratory technicians was published in *THE JOURNAL*, Aug. 29, 1936 together with the first list of 96 approved schools. Essentials had been formulated by the Council on Medical Education and Hospitals of the American Medical Association with the cooperation of the American Society of Clinical Pathologists and ratified by the House of Delegates of the American Medical Association in May 1936.

Last year 53 schools for clinical laboratory technicians were approved by the Council, resulting in a total of 227 approved schools. All of these approved schools are associated with hospitals providing adequate supervision as well as an adequate amount of teaching material to insure the students a wide scope of experience and training. Only 50 of the schools have a maximum enrolment of 10 or more students.

The 1,008 graduates reported for 1942 represent an increase of only 91 students over the previous year, even though a large number of schools were added to the approved list. Actually there was a decrease in the average number of graduates and students per school. The reader is referred to page 1020, where a table compares the number of technicians employed in 1941 with those employed in 1942. This indicates that a definite increase in the demand for technicians has been prevalent, while information from other sources points to a continued demand. Numbers of qualified technicians have been withdrawn from the hospitals and placed in defense industries, while the WAVES and the WAACS are enlisting many technicians for the armed forces. With such a small increase in the number of graduates from approved schools in the face of an apparent continued demand for technicians it is thought that every justifiable effort should be made to increase the number of students during the current year.

In view of the fact that the demand for technicians is increasing, the Council has recommended that the ratio of students to instructors be increased to a maximum of two students for each instructor. The continued efficiency of the practical instruction is made possible by reliance on the prerequisite college training which forms a background for the understanding of tests used in the hospital laboratory. By increasing the maximum

number of students actually trained in each laboratory, it is believed that an adequate supply of clinical laboratory technicians will be available for civilian needs. If a sizable number of technicians is withdrawn from civilian positions for the armed services it is thought that additional efforts should be made to increase the number of students in each of the approved schools. Most of the schools located in areas employing large numbers of defense workers find it difficult to maintain their usual number of students. This condition makes it necessary for the other schools to exert more energy in obtaining and training a larger class if the demand for technicians is to be relieved.

Sixty-four per cent of the approved schools require two years of preliminary college training for entrance. Several require three years of college training, while 15 per cent require a degree from an acceptable college. The two schools admitting students directly from high school are affiliated with colleges and require a training period of four or five years, which includes all the prerequisites for admission to an approved school.

The length of the training program in the hospital laboratories is twelve months in 80 per cent of the schools. Other programs range from thirteen to twenty-four months in duration.

One hundred and five of the schools report that affiliations have been made with accredited colleges. In 77 instances these affiliations permit the student to receive college credit for the time devoted to the hospital training of the student technician. This credit ranges from one-half semester to two years, but the majority of the affiliations result in a complete year of college credit.

Although the tuition varies from nothing to \$300, 54 per cent of the schools charge no tuition. The average tuition is \$49, while only 15 per cent of the schools charge a tuition of more than \$150.

Correspondence regarding schools for the training of clinical laboratory technicians should be addressed to the office of the Council on Medical Education and Hospitals. Graduates of approved schools desiring registration should communicate with the Board of Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind.

APPROVED SCHOOLS FOR CLINICAL LABORATORY TECHNICIANS

Council on Medical Education and Hospitals of the American Medical Association

NOTE Under "Tuition" the letter B indicates that a breakage fee is charged the letter U indicates university fees Degrees mentioned in last column are granted by affiliated colleges and universities
Students lacking the scholastic requirements should contact the registrar of the college or university and not the hospital Those who wish to enroll in a course given by the college or university or who desire to transfer their credits should correspond with the registrar and not the hospital

PHYSICIANS MUST VOLUNTEER FROM LARGE CITIES

At a recent meeting in Washington of the Directing Board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians with the Officer Procurement Service of the United States Army and with representatives of other governmental agencies, evidence was clearly set forth that the procurement of medical officers for the armed forces is lagging. The responsibility rests unquestionably on the failure of young available physicians in the large cities of the country, particularly those of the eastern seaboard, to volunteer. Officers of the medical societies of New York, Massachusetts and Connecticut were present and the situation was placed before them. The rural areas of the United States have contributed doctors not only up to such quotas as were assigned to them but in many instances well beyond these quotas, it is simply impossible to anticipate that they will make a further contribution at this time. In the meantime, New York, Brooklyn, Boston and some of the larger communities in the states of Connecticut, New Jersey, Pennsylvania and California have failed even to approximate their quotas.

The needs of the armed forces for physicians during 1943 are well defined. The number of physicians to be expected from recent graduates, interns and those now holding residencies has been determined. Beyond this number at least six thousand more physicians must come from the civilian population. The Procurement and Assignment Service for Physicians, Dentists and Veterinarians has devised a technic which involves, first a determination of the availability of the physician concerned or his essentiality for any civilian position which he occupies, second, notification of the physician of his availability and a request that he appear before his local procurement board, third, a notification of the Selective Service Board of the fact that the physician concerned is considered available and that he has failed to volunteer. Thus far pressure beyond this

has not been exercised. There remains, however, the mobilization of the pressure of public opinion.

In some instances physicians have declared flatly to representatives of the Procurement and Assignment Service and the Officer Procurement Service that they do not wish to volunteer and that they will not volunteer. When it is known to other physicians in the community that a physician under 38 years of age, declared available by the Procurement and Assignment Service, refuses to volunteer in this time of the nation's need, when many an older physician, frequently with innumerable obligations, has given up his home, his practice and the responsibilities of years to participate in this war, the public has a right to know that the younger physician is not willing to do his part. Certainly the Procurement and Assignment Service should consider the possibility at this advanced stage of the war effort of making public through the state medical journals not only the names of those who are already participating in the war but also the names of those who have been declared available and have not themselves ever indicated a willingness to participate. Let them be called before the bar of public opinion!

BIRTHS IN HOSPITALS

Data collected by the Council on Medical Education and Hospitals indicate that the number of births occurring in the hospitals on the list of registered hospitals maintained by the Council increased from 708,889 in 1931 to 1,404,940 in 1941 and to 1,670,599 in 1942. Apparently 27.9 per cent of the increase in the number of patients admitted to the hospitals of the country in 1942 over 1941 was due to the admission of an increased number of maternity patients. Although it is recognized that the data collected do not include all births occurring in all hospitals in the United States, they are sufficiently complete to warrant their use in computing the percentage of births occurring in hospitals, using as a base the total births recorded by the Bureau of Census of the U. S. Department of Commerce.

The table on page 1018 provides a striking picture of the increasing use of hospitals for obstetrics. The percentage of births occurring in hospitals for the country as a whole increased from 33.6 in 1931 to 55.9 in 1941. In New Jersey and the District of Columbia more than 90 per cent of the births recorded by the Bureau of Census for 1941 occurred in hospitals, while in five additional states more than 75 per cent of the births occurred in hospitals. In thirty states more than 50 per cent of the births were in hospitals. In only six states were less than 25 per cent of the births in hospitals, whereas in 1931 there were eighteen states in this category.

While there are many factors involved in maternal morbidity and maternal mortality, an inverse relationship seems to prevail between death rates for "diseases

of pregnancy, childbirth and the puerperium" and the percentage of births which occur in hospitals. According to the Bureau of Census reports¹ the death rate (number per hundred thousand of population) for these diseases for 1941 for the country as a whole was 60. The rates for the individual states varied from 32 to 155. In eleven states death rates for these diseases exceeded 80, and in none of these states did as many as 50 per cent of the births occur in hospitals. Furthermore, none of the six states with 75 per cent or more of its births occurring in hospitals showed a death rate for the diseases associated with childbirth as high as 50. However, the District of Columbia, with 93.8 per cent of births occurring in hospitals, showed a death rate of 67.

MUSCULAR EXERCISE AND FATIGUE IN DISEASE

Since 1900 many investigators have studied patients during and after muscular work. Simonson and Enzer² present an analytic review of such investigations of the gaseous exchange and the circulatory and respiratory functions. Distinctions between demonstrable fatigue and complaints of fatigue must be established by precise objective methods. Following analysis of the effect of disease on performance in various types of work, it might be possible to direct patients with chronic diseases toward occupations in which their working capacity would be least reduced. Control of the tax on their working capacity would be good therapy. Investigation during work permits a better understanding of the patient's actual condition than examination during rest. The patient may still be fully compensated while at rest but not for the increased demands during and immediately after muscular work. Thus the investigation of patients by means of exercise tests is especially important for those on the verge of cardiac decompensation. The state of the patient depends more on the interrelation of several functions than on any single function. Investigations during muscular work will help to recognize the weakest point at which decompensation is most likely to occur.

When the problem is viewed from this aspect, disease may be defined as "diminution of working capacity." Hence the measurement of the maximum working capacity should be an ideal method by which to determine the extent of the damage produced in the organism by pathologic processes. Severe lesions of the heart do not necessarily impair maximum performance for muscular work. Apparently it is not the primary

lesion but the breakdown of the compensatory mechanism which leads to signs and symptoms of circulatory insufficiency.

Among the methods used to measure maximum working capacity, a number of investigators were concerned with the rate of maximum oxygen intake. Measurement of the maximum oxygen intake is an indirect method for determining the maximum minute volume of the heart, provided the pulmonary system is intact. The decrease of the maximum oxygen intake was found proportional to the degree of insufficiency for working condition, that is, to the decrease of the circulatory reserve. The decrease was especially pronounced for patients with mitral stenosis, whose maximum oxygen intake reached only the value of 200 to 300 cc per minute. This is only slightly above the resting stage of oxygen consumption. The rate of maximum oxygen intake is a reliable index of cardiac reserve, provided pulmonary complications are not involved. In the latter case the maximum oxygen intake indicates the capacity of the respiratory and circulatory systems. If the maximum oxygen intake exceeds a value of 1,300 cc per minute it may be assumed that there is no circulatory insufficiency. This is an objective method, although it depends on the patient's cooperation to work with maximum effort. Another objective method involves measurement of the maximum oxygen debt, which is the excess oxygen consumed during the recovery period. The maximum oxygen debt is lower in patients with heart disease.

Investigations of this type brought out some interesting facts. Efficiency in any type of work is considerably reduced in patients with hyperthyroidism. The deviations of efficiency here are much greater than in heart disease. In beginning toxic diffuse goiter the coefficient of efficiency may be decreased before the basal metabolic rate is elevated. Thyroidectomy leads to a consistent improvement of the efficiency, while the improvement of the basal metabolic rate was not as consistent. Thus it appears that the coefficient of efficiency more nearly parallels the seriousness of the disease than does the increase of the basal metabolic rate and therefore might be of considerable diagnostic and prognostic value. Another important index in the analysis of pathologic conditions is the speed of oxidative processes. This may be determined during and after exercise by measuring (a) the speed of the increase of oxygen consumption during the period of adaptation (the first five minutes of work), (b) oxygen debt and (c) recovery speed. Oxygen debt is contracted during the period of adaptation, so that the increase of oxygen consumption during the adaptation period is the fundamental process to which the final oxygen debt is related. The oxygen debt is considerably increased in patients with heart disease, and the

¹ Vital Statistics, Special Reports, Deaths from Selected Causes, United States 1941, 17, Dec 9, 1942.

² Simonson, Ernst and Enzer, Norbert. Physiology of Muscular Exercise and Fatigue in Disease. *Medicine* 21: 345 (Dec.) 1942.

increase parallels the degree of symptoms of decompensation. Hence the measurement of the oxygen debt would seem to be an ideal method for evaluating the state of patients with heart disease. Oxygen debt has been found to be increased in chronic bronchitis, emphysema, advanced lung tuberculosis and pronounced silicosis. Oxygen debt reflects the delay of oxidative processes during the adaptation period.

On the basis of the investigative data the reviewers conclude that there is a quantitative rather than a qualitative difference of physiologic processes in exercise in disease. Fatigue and disease are intimately related. This relationship explains why fatigue is the most common complaint in disease.

Current Comment

THE NATIONAL CONFERENCE ON PLANNING FOR WAR AND POSTWAR MEDICAL SERVICES

More than seven hundred and fifty physicians and leaders in allied medical industries assembled in New York on March 15 to attend a Conference on Planning for War and Postwar Medical Services. The program served to focus the attention of the medical profession and the interested public on the nature of the problems peculiarly medical which will confront all the world, but particularly the medical profession of the United States, in the postwar period. The morning session was devoted to tropical diseases, especially malaria, influenza and the problems of nutrition. The afternoon session concerned medical and surgical supplies, personnel and research. At the dinner addresses were delivered by Mr. Basil O'Connor, as president of the National Foundation for Infantile Paralysis and president of the Finlay Institute of the Americas; Mr. Fred Keppel of the Carnegie Foundation; Richard Allen of the Red Cross, who has just returned from a trip to North Africa and the Near East; Mr. Nelson Rockefeller, Coordinator of Inter-American Affairs; and Dr. Morris Fishbein, Editor of *THE JOURNAL*. Those in attendance at this conference were enthusiastic in their comments concerning the program. The papers taken as a whole, emphasized the diversity of the problems and the importance of maintaining health as a first step in restoration and rehabilitation of a devastated world. Emphasis was placed especially on the desirability of establishing a single, well organized planning committee charged with coordination of the many medical advisory and similar bodies now associated with such agencies as the Board of Economic Warfare, the Lend-Lease Administration, the Joint Army and Navy Purchasing Board, the American Red Cross, the National Research Council and the many departments and bureaus of the federal government. The papers and the discussions emanating from this conference will be published in *THE JOURNAL* in the near future.

HOSPITAL RESIDENTS AND MEDICAL EDUCATION

Recent advances in medical education have involved the assignment of third and fourth year students in groups to the wards of the teaching hospitals and to the outpatient departments. Under competent supervision students receive their training by actual experience with patients and associated studies rather than merely by the study of textbooks and the demonstration of patients in amphitheater clinics. These developments represent one of the most significant advances in professional education. Such programs have been possible only because there were available in the teaching wards of the hospital and in the outpatient clinics a sufficient number of younger well trained faculty members and an adequate staff of resident physicians to provide adequate supervision of the students and to participate in the thorough study of the patients. Practically all younger faculty members are now serving with the military forces, this places even greater responsibilities on the resident staff. Internships are now limited to one year, which means that the intern is called to serve with the armed forces just when he is sufficiently well trained to function as an efficient house officer. Today the great responsibility of medical education is the provision of as many competent physicians as possible in the shortest possible time. The medical schools have adopted minimum admission requirements and have accelerated their programs. However, an adequate number of assistant residents and residents must be available in the clinical teaching services of the medical schools of the country if even reasonably satisfactory standards of clinical teaching are to be maintained. Practically all medical school graduates are subject to call to active duty by either the Army or the Navy. These branches of the armed services in cooperation with the Office of Procurement and Assignment have given much attention to the problem. No doubt a satisfactory program will be formulated which will make available to the medical schools enough competent residents to provide satisfactory training for the students.

HOLMES AND PUERPERAL FEVER CENTENARY CELEBRATION

On Feb. 19, 1843 Dr. Oliver Wendell Holmes first read his paper on the contagiousness of childbed fever before the Boston Society for Medical Improvement. In celebration of the centennial of this event—the importance of which to maternal health is so well known to the medical profession as scarcely to require remark—an all day conference on Maternal Health and Child Welfare was held in New York on Feb. 19, 1943. It is wholly fitting that this anniversary of Holmes's great contribution, as discussed elsewhere in this issue by Daily (p. 1006), should be signified by widespread recognition on the part of the medical profession.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

GENERAL HOSPITALS DESIGNATED FOR SPECIAL SURGICAL TREATMENT

The War Department, Washington, D C, on March 6 issued the following memorandum

1 It has become evident that certain diseases and injuries will require treatment of a surgical nature in which a high degree of specialization is necessary The following general hospitals have therefore been designated for the special surgical treatment indicated

(a) Chest surgery

Fitzsimons,	Denver
Hammond,	Modesto, Calif
Kennedy,	Memphis, Tenn
Walter Reed,	Washington, D C

(b) Maxillofacial and plastic surgery

Bushnell,	Brigham, Utah
O'Reilly,	Springfield, Mo
Valley Forge	Phoenixville, Pa
Walter Reed	Washington D C

(c) Amputation centers

Bushnell	Brigham Utah
Lawson	Atlanta Ga
McCloskey,	Temple Texas
Percy Jones	Battle Creek Mich
Walter Reed,	Washington D C

(d) Ophthalmic surgery and treatment of blinded casualties (including maxillofacial and plastic surgery involving the eye)

Letterman	San Francisco
Valley Forge	Phoenixville, Pa

(e) Neurosurgery

Ashford	White Sulphur Springs W Va
Brooke	San Antonio Texas
Bushnell	Brigham, Utah
Fitzsimons,	Denver
Hoff	Santa Barbara Calif
Kennedy,	Memphis, Tenn
Lawson,	Atlanta Ga
Lovell	Fort Devens Mass
McCaw	Walla Walla Wash
McCloskey,	Temple Texas
Nichols	Louisville, Ky
O'Reilly	Springfield Mo
Percy Jones,	Battle Creek Mich
Schick	Clinton Iowa
Tilton	Fort Dix N J
Walter Reed	Washington D C

2 Patients received from overseas who require the specialized treatment indicated will be classified by the general hospitals receiving them and reported to the Surgeon General for transfer to designated specialized hospitals

By order of the Secretary of War

J A ULIO,
Major General, the Adjutant General

CONTRACT SURGEONS WANTED

The surgeon of the Seventh Service Command writes that contract surgeons, both male and female, are wanted at army operated industrial plants and depots in Colorado, Missouri, Nebraska, Kansas and South Dakota The pay, with dependents, is about \$3,400 a year For further details write the Surgeon, Headquarters Seventh Service Command, Federal Building, Omaha, Neb

REJECTION OR DISCHARGE FOR PSYCHIATRIC REASONS

The War Department, Washington, D C, on March 5 issued the following memorandum

1 Men rejected by induction stations and those discharged from the Army by CDD for psychiatric reasons have suffered severely from the injudicious manner in which some of these cases have been rejected or discharged In some instances men who have been returned to the community were told that they were 'crazy' or were given some other equally tactless reason As a result they have suffered severely from the shock to themselves and from the attitude of others in the community who learned of the reason for rejection

2 Since this problem exists, all medical officers concerned with the rejection or discharge of men for psychiatric reasons will use painstaking tact in making the individual aware of the fact that he would be unable to adapt himself to the rigors of army life and that he could serve his country better in a defense industry or other gainful occupation Any other suitable reason may be given In this manner the reason for the person's returning to the community can be explained to him, and the frame of mind in which he is returned to civilian life can be dealt with in such a way as to avoid severe hardship and may possibly help to salvage that person for some gainful occupation at a time when all available manpower is essential

3 Letters sent from some army hospitals to relatives of soldiers who are mentally ill have in many instances not been worded in sympathetic language Some letters have been harsh and unsympathetic and have come as a shock to distraught relatives who for the first time may have been made aware of the soldiers' illness Much can be done for public morale and confidence in the medical department if all concerned will take immediate steps to make certain that letters to relatives of mentally ill soldiers are written in a sympathetic and tactful manner Such letters will contain no statement to the effect that the soldier is not entitled to future hospitalization, since this question is one for the Veterans Administration and not for the Army to decide

By order of the Secretary of War

J A ULIO,
Major General, the Adjutant General

THE NICHOLS GENERAL HOSPITAL IN LOUISVILLE

The Nichols General Hospital in Louisville, Ky, was transferred to the Medical Department, U S Army, by the Corps of Engineers on Nov 16, 1942, the date of completion of construction, and following a short period for equipping the several departments, wards and clinics and the organization of the staff the hospital was made ready for the reception of patients on Jan 15, 1943 The hospital is of standard mobilization type construction consisting of one story frame buildings with intercommunicating corridors Military patients are currently being drawn from outlying posts, camps and stations with facilities in readiness for the receipt of overseas patients

The chiefs of the professional services are as follows: medical, Major Thomas J White, surgical, Col S C Woldenberg, neuropsychiatric Major Orr Mullinax, roentgenology, Major Anthony C Galluccio, dental, Lieut Col Emil L Aison, and laboratory, Major Louis R Ferraro

THE KENNEDY GENERAL HOSPITAL AT MEMPHIS

The U S Army Kennedy General Hospital in Memphis, Tenn, was dedicated January 27 and 28 of its 102 two story brick buildings of colonial architecture are already in use, many of the patients under treatment being battle casualties. When completed in May the hospital will have 3,000 beds, making it one of the largest army hospitals. The city of Memphis donated to the government the site of 144 acres, which only last spring were still cotton farms and woodland. More than 38,000,000 man hours of labor will have been performed, about 180 miles of electric wire and cable and 24 miles of sprinkler pipes will have been laid and more than 14,000,000 board feet of lumber will have been used when the hospital is finished. There will be more than 2 miles of covered corridors and 3 miles of roadway.

The War Department named the hospital as a memorial to the late Brig Gen James W Kennedy, a member of the medical corps for thirty-six years. General Kennedy had been cited for gallantry in action during the Spanish American War and awarded both the Distinguished Service Medal and the Navy Cross for his service as port surgeon at Hoboken, N J, during the first world war. Among those at the dedication ceremonies were Major Gen James C Magee, Surgeon General of the Army, Brig Gen Max C Tyler, engineer in charge of the hospital construction, the Honorable Walter Chandler, mayor of Memphis, Dr James B Stanford, president of the Tennessee State Medical Society, Mrs James M Kennedy and her daughter, Mrs Kean.

The commanding officer of the Kennedy General Hospital is Brig Gen Royal Reynolds, brother of the former surgeon general Charles R Reynolds and of Col Frederick P Reynolds, M C, U S Army, retired, former executive secretary of the New York Academy of Medicine. The executive officer is Lieut Col Hugh L Prather, M C. The chiefs of services now on duty are as follows: Col John N White, D C, chief of Dental Service, Lieut Col Francis J McGowan, M C, chief of Surgical Service, formerly visiting surgeon, St Vincent's Hospital, New York City, Major Vernon E Powell, M C, chief of medical service, formerly assistant in medicine, Emory University School of Medicine, Atlanta, Major Emmerich von Haam, M C, chief of laboratory service, formerly instructor in pathology, Ohio State University, Columbus, Major Justin E McCarthy, M C, chief of x-ray service, formerly assistant attending radiologist, University of Cincinnati, and Capt Rusk in G Anderson, M C, chief of eye, ear, nose and throat service, formerly of the Spartanburg General Hospital, Spartanburg, S C.

BRIGADIER BRISTOW VISITS CARLISLE BARRACKS

Brigadier Rowley Bristow of the British Army Staff on February 25 addressed the garrison and student officers at the Medical Field Service School, Carlisle Barracks, Pa, on the treatment of gunshot wounds. Brigadier Bristow, who is a consultant in orthopedics in the British Army and a professor at the University of London, stressed the late advances in the treatment of wounds and compound fractures by the closed plaster method. In World War I he worked with Sir Robert Jones at the Orthopedic Center at Shephard Hospital in London after having served as a battalion surgeon in Gallipoli.

AVIATION PHYSIOLOGISTS

Another class of aviation physiologists graduated at the School of Aviation Medicine in Texas on February 27. The course of instruction treats of the effects of lowered barometric pressure, anoxia and the effect of flight on man, the operation of low pressure chambers, the theory and practical use of oxygen equipment, and the conduct of high altitude indoctrination and classification. Among the graduates were the following medical officers: Capts Broda O Barnes, Denver, George R Crisler, Winter Park, Fla, and First Lieuts Joseph Beinstein, Wilkes-Barre, Pa, Michael L Gompertz, New York, Eugene M

Hartnett, Drexel Hill, Pa, Charles W Klanke, Houston, Texas, Max A Lundauer, Philadelphia, Robert W Ollajos, Hamden, Conn, Frederick F Rogers, Dilley, Texas, Robert W Smith, Owensboro, Ky, Frederick S Sperry, Clarina, Iowa, William F Weeks, Highland Park, Mich, George W Wilkinson, Laurel, Iowa, Edward T Wilson, Chicago, and Norman L Zahrt, Iowa City.

MAJOR RUSK IN CHARGE OF RECREATION AND RECONDITIONING PROGRAM

Major Howard A Rusk, formerly of St Louis, who has been chief of the medical service at the Station Hospital, Jefferson Barracks, Mo, has been transferred to Washington, D C, and assigned to the staff of Brig Gen David D W Grant, the air surgeon, to be in charge of the recreation and reconditioning program for hospital patients for all army air corps hospitals. Major Rusk initiated a novel program for convalescent soldiers while at Jefferson Barracks whereby they were taught during the period of convalescence by means of lectures, moving pictures and other types of visual education and physical exercises. This program includes instruction in chemical warfare, camouflage, radio, model airplane building, a refresher course in mathematics, a basic course in military discipline and a course for illiterate soldiers. The primary purpose of this program is to make use of the time ordinarily lost during convalescence by giving the men instruction in the technical courses needed by the air forces. This program was initiated at Jefferson Barracks under the supervision of Col James R McDowell, commanding officer of the hospital, and Brig Gen David D W Grant, the air surgeon. Before entering the service, Major Rusk had been in private practice in St Louis for many years, where he was associate chief of staff at St Luke's Hospital and instructor of medicine at Washington University School of Medicine.

VENEREAL CLINIC AT RECEPTION CENTER

The commanding officer of the reception center at New Cumberland, Pa, has announced the opening of a new hospital unit which will function as a clinic and will have as its chief function the rehabilitation of men who previously had been rejected because of venereal disease. The clinic will deal primarily with newly inducted soldiers and will be in constant contact with health and social agencies, which will follow up on the sources of infection of the soldiers. The clinic is completely and modernly equipped, having its own mess hall, laboratory and pharmacy and, although an independent unit, will function with the regular infirmary. The Venereal Facility will be under the supervision of Capt Russell R Rubba. The administration officer will be Second Lieutenant Paul R Whipp of the Medical Administrative Corps.

SPECIAL TRAINING COURSES

Nineteen officers of the Medical Department of the Army graduated at the Medical Field Service School, Carlisle Barracks, Pa, March 5, from a special training course and left immediately for assignments in the medical battalions in infantry divisions now being activated. Of the nineteen officers, eighteen hold commissions in the medical corps and one in the medical administrative corps. The officers represented eleven states. Another special course began on March 8.

PURPLE HEART AWARDS

The War Department recently announced the award of the Purple Heart to Capt Alfred T Leminger and Lieut Howard H Angell, both of the medical corps, for wounds received in action at Clark Field, near Manila, Philippine Islands, Dec 8, 1941. Captain Leminger's home is in Wayside, Wis, and Lieutenant Angell's home is in Saginaw, Mich.

NAVY

NAVY CONSULTANT BOARD

The Surgeon General of the U S Navy convened in Washington in December a Board of Honorary Consultants, whose counsel was desired on subjects vital to the naval medical service. The board, after a two day session, submitted a report covering brain surgery, anesthesia, chest surgery, psychotherapy, the psychoneuroses and other subjects. Members of the board of consultants were Dr Donald C Balfour, director of the Mayo Foundation, Rochester Minn, Dr George W Crile, director of the Cleveland Clinic Foundation, Cleveland, Dr Walter E Dandy, professor of neurosurgery at Johns Hopkins Medical School, Baltimore. Dr Frank H Lahey of the Lahey Clinic Boston, and head of the Procurement and Assignment Service, Dr Oswald L Lowsley, New York, Dr Willis B Morse, Salem, Ore. Dr William A Sawyer, New York, director of the International Health Division, Rockefeller Foundation, and Dr Meyer Wiener, professor of clinical ophthalmology, Washington University School of Medicine, St Louis. Dr Crile, who did not attend the conference, died on January 7.

CLASS OF NAVAL MEDICAL OFFICERS

The following medical officers completed the basic course of instruction at the Naval Medical School, Bethesda, Md, February 6. Included are the dates and places at which these officers served their internships. All of these officers at the time of the graduation were lieutenants (jg) except Drs Hope, Kinne and Myer, whose rank was that of lieutenant.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS,
DENTISTS AND VETERINARIANSUTILIZATION OF PERSONNEL RESULTING
FROM OVERLAPPING OF INTERNSHIPS

The directing board of the Procurement and Assignment Service has informed its state chairmen that consideration should be given to overlapping internships resulting from the nine months school year and has suggested that state chairmen should serve as a clearing house between hospitals with such overlapping internships and institutions requiring additional personnel.

Nearly all medical schools now have a graduating class each nine months. A full year internship now is required by Army and Navy regulations, by many state boards and, in some instances, by medical schools. In March and April new groups of interns are entering hospitals for their internships with interns from last year still having three or more months left to complete their required service.

It is the consensus of organizations concerned, sitting with representatives of the three surgeon generals and of Selective Service that there would be no objection to utilizing these overlapping internships elsewhere, such as in approved hospitals without adequate personnel, if the hospital in which the first part of the internship was served will certify to a full year's service. This opinion was concurred in by representatives of the Council on Medical Education and Hospitals of the American Medical Association the Advisory Board for Medical Specialties, the Federation of State Medical Boards, the Ameri-

can Hospital Association, the American College of Surgeons, the Protestant Hospital Association, the Catholic Hospital Association and the Association of American Medical Colleges.

NURSES IN PROCUREMENT
SERVICE OFFICES

Under a new policy of the War Department, a nurse will be placed in each of the 38 field offices of the procurement service. According to the *Army and Navy Journal* of February 27, these 38 assignments of chief nurses in these offices was to have been completed by March 1. These nurses will interview applicants, evaluate their aptitude for the Army Nurse Corps and fill speaking and radio engagements in support of the drive for additional nurses. Much of the time of these nurses will be spent with local Red Cross officials, who have the primary responsibility of recruiting nurses for the Army. A total of 13,000 nurses was obtained in the calendar year 1942, and by March recruitment is expected to average 2,500 a month. By the end of this fiscal year, June 30, 1943, a total of 31,000 nurses is expected to be in service. There was a party at Aberdeen Proving Ground, Md, February 27, to honor the Army nurse. A special guest at the festivities was Lieut Col Florence A Blanchfield acting superintendent of the Army Nurse Corps. The commanding general and other officers at Aberdeen were present.

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the medical department of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 10-30 p m (formerly heard at 8 p m) Saturdays over station WMAQ. Unless otherwise indicated, each program is summarized by Dr W W Bruer, Director, Bureau of Health Education.

The titles and speakers for the next four programs are as follows:

April 3 The White Plague 1943 Speaker Dr Kendall Emerson
Managing Director National Tuberculosis Association
April 10 Battle Stations at Home Speaker Col George Bach
Chief Medical Officer Office of Civilian Defense

April 17 "Stratosphere Flight" Speaker Brig. Gen. David N W
Grant Air Surgeon United States Army
April 24 Ship Eyes Speaker Lieut. Col. Harold C Lueth, Liaison
Officer Procurement and Assignment Service Chicago

BEFORE THE DOCTOR COMES

The American Medical Association program on radio station WLS (890 kilocycles) entitled Before the Doctor Comes will be on the air every Thursday morning at 9-45 up to and including May 27. This program is intended to be helpful to the mothers of young children. Mrs. June Merrill will interview Dr W W Bruer, Director of the Bureau of Health Education, on common home health problems. The titles for the next four programs are:

April 1 The Child with Parrot
April 8 What to Do About Cuts and Scratches
April 15 What to Do About Bad Numps
April 22 What to Do About Cholera

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S 786 has passed the Senate and House, providing rehabilitation for disabled veterans of World War II. A subcommittee of the House Committee on Military Affairs has approved a bill introduced by Representative Sparkman, Alabama as H R 1857 to provide for the commissioning of female physicians in the Medical Departments of the Army and Navy. The subcommittee eliminated from the bill a restriction that such female physicians should be assigned only to duty in hospitals or stations where female nurses are employed. H R 1936 has passed the House authorizing an appropriation of \$2,000,000 to expand the facilities for hospitalization of dependents of Naval and Marine personnel and for certain persons outside the continental limits of the United States.

Bills Introduced—S 1 Res 43, introduced by Senator Davis, Pennsylvania, proposes to authorize the appropriation of such sums as may be necessary to establish a Division for the Physically Handicapped in the United States Employment Service. S 876, introduced by Senator Hayden, Arizona, would authorize an appropriation for the fiscal year 1943 of \$2,884,000 and not to exceed \$10,000,000 for any fiscal year thereafter for payment to states for expenditure in accordance with state plans for the wartime care and protection of children of employed mothers. H R 2158 introduced by Representative Gray, New York, provides that if a person who served in the military forces of the United States during the period beginning Dec 7, 1941 and ending on the date on which the President proclaims that hostilities have ceased is honorably discharged from such service for disability, the disability shall be held to have been incurred in or aggravated by active service in the line of duty, unless it is proved that such disability existed prior to induction or enlistment or is of a congenital nature. Each such person on being discharged from the service will be furnished by the Veterans Administration such care and treatment as may be necessary to rehabilitate him for employment in a useful or gainful occupation.

STATE MEDICAL LEGISLATION

Arizona

Bill Introduced—H 214 proposes to require every applicant for a marriage license to file a certificate executed by a licensed physician certifying that in the opinion of the physician the applicant is not infected with syphilis or gonorrhea.

Bill Enacted—H 25 has become chapter 26 of the Laws of 1943. It enacts an occupational disease law and contains a list of some thirty-five diseases which shall be deemed to be occupational in nature, among which are asbestosis and silicosis.

Arkansas

Bill Enacted—H 432 was approved, March 11. It prohibits the sale of appliances, drugs or medicinal preparations having special utility for the prevention of conception or venereal diseases without a license issued by the state board of pharmacy but excepts physicians and medical practitioners regularly licensed to practice medicine or osteopathy from the provisions of the proposal.

Colorado

Bills Passed—H 199 passed the house March 13. To amend the chiropractic law, it proposes to require chiropractors at the time of the annual renewal of their licenses to present proof that they have attended at least three days of a scientific clinic forum or educational study approved by the Colorado state board of chiropractic examiners. H 200 passed the house March 13. Proposing to authorize the chiropractic board to adopt a schedule of minimum educational requirements for chiropractic schools to be not less than 3,600 sixty minute hours of classroom instruction with a maximum of thirty hours per week and covering a period of not less than four years of nine months each, the bill was amended in the house by striking therefrom the requirement that the course of instruction cover a period of not less than four years of nine months each.

Connecticut

Bill Introduced—Substitute for S 249 proposes to authorize veterans of the first world war or the second world war and persons in the armed forces of any government associated with the United States in either of said wars who are citizens of the state to receive temporary financial assistance from the veterans' home commission.

Delaware

Bill Enacted—S 38 was approved, March 4. It authorizes the medical council of Delaware to issue temporary emergency certificates to physicians licensed outside the state and to make such regulations, restrictions and area limitations concerning such temporary licenses as it deems necessary. Furthermore it provides that an internship of nine months shall be required of applicants for a license to practice medicine and surgery in addition to the other qualifications set forth in the medical practice act. The prior law required an internship of one year.

Georgia

Bill Introduced—H 613, to amend the uniform narcotic drug act proposes to exempt therefrom the administering, dispensing and selling of certain attenuated narcotic preparations.

Bill Passed—H 552 passed the senate, March 15. It proposes the abolition of the state boards of medical examiners, chiropractic examiners and osteopathic examiners and the creation in their stead of a State Commission of Medical Examiners, Georgia Commission of Chiropractic Examiners and State Commission of Osteopathic Examiners of Georgia. The powers, duties and qualifications would be the same except that members appointed by the governor must be approved by the secretary of state and confirmed by the senate.

Illinois

Bill Introduced—H 264 proposes the creation of a chiropractic board by the Department of Registration and Education and defines chiropractic as the science of palpating and adjusting the articulations of the human spinal column, correcting interference with nerve transmission and expression, to restore health, without the use of drugs or surgery.

Indiana

Bills Enacted—S 4 has become chapter 158 of the Laws of 1943. It provides for the licensing and regulating of nursing homes but exempts therefrom treatment in a private household and in any hospital, home or institution conducted by or for the members of any religious body or denomination or regularly organized patriotic, fraternal or charitable organization. The law provides that it shall be unlawful to conduct a nursing home unless the treatment and care of inmates therein is in charge of a registered nurse and defines the term "practical nurse" as a person who has had not less than one year's experience in caring for sick persons under the direction of a duly licensed practicing physician. S 135 has become chapter 162 of the Laws of 1943. It prohibits school authorities from employing food handlers who are addicted to drugs or who have tuberculosis or syphilis in an infectious stage and requires all school employees to undergo a physical examination for tuberculosis at least once every three years by a duly licensed doctor of medicine. H 66

has become chapter 264 of the Laws of 1943. It provides for the regulation of plants for the cold storage of food and provides that all employees of such locker plants shall undergo a semiannual health examination by a physician. Furthermore, the law prohibits the employment of any person suffering from a communicable disease including any communicable skin disease or with infected wounds, and any person who is a carrier of a communicable disease.

Iowa

Bill Passed—S 82 passed the house March 12. To amend the income tax law, it proposes to authorize taxpayers to deduct expenses for the medical care of the taxpayer, and the term "medical care" is defined as amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body. A senate amendment of February 18 proposes to allow also a deduction for treatment or nursing as prescribed by a well recognized church or religious denomination in a hospital or sanatorium conducted by such church or denomination.

Maine

Bills Introduced—S 303 to amend the osteopathic practice act proposes that the requirement of attendance of at least two days at an annual educational program as a condition for the renewal of an osteopathic license be suspended until six months after the cessation of hostilities in the present war. S 304 to amend the osteopathic practice act proposes to authorize approved osteopathic schools to give a course of instruction for a total of thirty-six months within a three to four year period when such school has adopted compressed or accelerated courses as a war emergency measure.

Bill Enacted—S 406 has become chapter 63 of the Laws of 1943. It amends the law providing for the payment of fees to expert witnesses by providing that all expert witnesses for the state in homicide cases shall be paid such amounts as the presiding judge allows and shall be paid by the state.

MEDICAL ECONOMIC ABSTRACTS

CHANGING TRENDS IN HOSPITALIZATION

The publication by the Bridgeport (Conn.) Hospital of statistics of many features of hospitalization since 1899 were analyzed in a previous article in this section (*THE JOURNAL*, March 30 1940, p. 1272). This showed that in forty years the average stay in the hospital had declined from 34 days in 1899 to 11.2 days in 1940 but had remained between 10 and 11.5 days for the last twenty years; also that the cost per patient day had increased in forty years from \$1.32 to \$4.91. The continuation of these figures through 1942 now shows some significant changes due to war conditions. While the average stay in the hospital has changed little, being 10.1 days for 1942 and the cost per patient day has continued to rise to \$5.96, the days of free service, which in 1931 were 25,426 and 10,248 in 1940 dropped to 162 for 1941 and 4,529 in 1942. While the number of days in the hospital has fallen more than 75 per cent, the average hospital cost per patient has shown a steady upward trend ever since the low point of \$26.72 of 1914 and reached \$59.34 in 1942.

BLUE CROSS HOSPITALIZATION DATA

A report of the Hospital Plan Commission of the American Hospital Association shows that almost one million patients were hospitalized by plans in 1942 when the average rate of admission was 108 patients per thousand participants. Average admissions in 1942 were 1 per cent greater than in 1941. Highest incidence for both years was reported in August and lowest in November 1941 and December 1942. Month to month trend of admission rates in 1942 followed the trend of 1941.

The three months with the highest percentage of subscribers hospitalized in 1941 and 1942 were June, July and August. This is a variation from the customary hospital bed occupancy of all hospitals, which show the highest percentage of occupancy from January to February inclusive,¹ which are also the months which customarily show the highest morbidity.

HOSPITAL SERVICE IN NEW YORK

Mr. Louis H. Pink, New York State Superintendent of Insurance since 1939, has announced his intention of leaving his present office December 31 to become president of the Associated Hospital Service of New York, filling the vacancy created by the death of Dr. S. S. Goldwater. This action takes place at the same time that the Hospital Service undertakes a large scale expansion of Community Medical Care, Inc., which is to furnish a prepayment surgical service to subscribers to the hospital plan.

Under the surgical plan, subscribers will continue to select and engage their own physicians. Costs for the surgical coverage are 40 cents per month for an individual contract, \$1 per month for a husband and wife contract and \$1.80 per month for a family group (husband, wife and children) contract.

Mr. Pink has been treasurer of the New York Child Labor Committee, chairman of the State Housing Board and member of the New York City Board of Education and of the New York City Housing Authority.

On Oct. 31, 1942, the New York Associated Hospital Service, although not yet 8 years old, had assets of \$9,894,082.99. In addition to a voluntary \$2,000,000 reserve for epidemics and other possible emergencies, it had a surplus of \$5,121,865.19 for protection of its subscribers.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ALABAMA

State Medical Meeting—The Medical Association of the State of Alabama will hold its annual session in the Tutwiler Hotel Birmingham, April 20-22, under the presidency of Dr Harvey B Searcy, Tuscaloosa. Among the speakers will be

Dr James E Cameron, Alexander City, The Perforating Peptic Ulcer
Dr James M Wsham, Talladega, The Surgical Consideration of Jaundice

Dr Chalmers H Moore, Birmingham, The Diagnosis of Brain Tumor
Dr John D Sherrill, Birmingham, Internal Derangements of the Knee Joint

Dr Hugh E Gray, Anniston, The Treatment of Compound Fractures

Dr Martin G Neely, Fairfield, Infants—and Overfeeding

Dr Charles K Pitt, Decatur, Rheumatic Infections in Childhood

Dr Carl A Grote, Huntsville, Constrictive Pericarditis, Report of Case

Drs Jasper D Bush Jr, University and Enoch M Mason, Birmingham, Coccidioidomycosis

Dr Harry A M Simpson, Florence, Functional Disorders of the Upper Gastrointestinal Tract

Dr Philip M Lewis, Memphis, Tenn., External Diseases of the Eye

Dr James E Paullin, Atlanta, Ga., President Elect of the American Medical Association, The Contribution of American Medicine to the War Effort

Dr Walter E Dandy, Baltimore, The Diagnosis and Treatment of Ruptured Intervertebral Disks

Dr James J Durrett, Washington, D C, Our Health and the Federal Trade Commission

Comdr Bartholomew W Hogan, medical inspector U S Navy, Washington, D C, The Navy Medical Corps in Combat Areas

Dr Oscar R R Troje, Fairfield, The Minority Opinion on Silicosis

A symposium on "The Sulfonamides—Their Usage in Pediatrics" will be presented by Drs Wallace A Clyde, Clifford L Lamar and Hughes Kennedy Jr, all of Birmingham. Dr Albert C Furstenberg, dean University of Michigan Medical School, Ann Arbor, will deliver the Jerome Cochran Lecture Wednesday on "Objectives in Medical Education." A round table discussion on dermatology will be held Wednesday evening by Drs Charles O King and Andrew L Glaze, Birmingham, on "Differential Diagnosis and Treatment of Fungous Infections of the Skin" and "Some Technical Office Procedures in Dermatology and Syphilology" respectively, and one on genitourinary diseases with Drs Robert M Cothran, Birmingham, on "Perinephric Abscess", Jesse U Reaves, Mobile, "Kidney and Ureteral Colic Unassociated with Calculus" and Jarratt P Robertson, Birmingham, "Ureterovaginal Fistula Following Hysterectomy."

COLORADO

The Bonfils Blood Bank—The Belle Bonfils Memorial Blood Bank was opened officially in Denver, February 27. The *Rocky Mountain Medical Journal* reports the project to be the only one under the Office of Civilian Defense between Omaha and Salt Lake City and to have been made possible by Miss Helen Bonfils, Denver, in memory of her mother. The blood donor center and the processing laboratory are located at the Colorado General Hospital, Denver. Plans for the unit resulted from the cooperation between the Medical Society of the City and County of Denver, the Denver Chapter of the American Red Cross, the Office of Civilian Defense and the Colorado General Hospital. The purpose of this bank is to maintain a reserve of blood plasma for the needs of the population in the event of possible civilian disaster in the Rocky Mountain region. Surplus of plasma accumulated beyond the requirements of the Office of Civilian Defense will be available for use by licensed physicians and hospitals of this region. Any additional reserve beyond these needs will be made available to the armed forces.

DELAWARE

Temporary Licenses to Practice—The board of medical examiners and the Medical Council of Delaware announced that the following applicants, all of Wilmington, have been granted reciprocal licenses to practice medicine and surgery in Delaware, in accordance with recent action by the legislature to grant temporary licenses for emergency measures: Drs Joseph M Orloff (Pennsylvania), Douglas Joseph Barry (New York), Margaret Pauline H Foulger (Pennsylvania), Paul Charles Johnson (New York), Lemuel C McGee (West Virginia) and William M Genthner (New York). The action was taken to assist in the placement of physicians in industrial

plants and in certain localities of the state where there is a shortage of physicians. On account of a bill passed by the legislature, the board of medical examiners will conduct examinations April 13-15 for those applying for a license to practice medicine and surgery in the state of Delaware. Delaware is apparently one of the first states to adopt this procedure. Similar legislation is under consideration by a number of states.

ILLINOIS

Health of Industrial Workers—The Kane County Medical Society and the Fox River Valley Manufacturers Association in cooperation with the state medical society, the state manufacturers association and the division of industrial hygiene of the state department of public health sponsored a conference on "Health of Industrial Workers" at Aurora March 10. Dr John W Dreyer, Aurora, presided, and Drs Orlen J Johnson, Chicago, spoke on "Better Local Industrial Health Organization." Milton H Kronenberg, Chicago, "Problem of Women in Industry," Paul A Brehm, Madison, Wis., "Absenteeism in Industry," and Edward C Holmblad, Aurora, "How the Small Plant Can Conduct a Health Program." A dinner meeting presided over by Dr Richard K Collins, Aurora, president of the Kane County Medical Society, with Mr W M Willett, Aurora, vice president of Western United Gas & Electric Company as toastmaster, was addressed by Arnold P Benson, Birtwin, president pro tem of the state senate, on "Why I Am Interested in Promoting an Industrial Health Program" and Dr Chauncey C Adler, Chicago, "The Health of the Executive."

Chicago

Supreme Court Refuses to Reconsider Abortion Case—The Illinois Supreme Court on March 11 refused to reconsider its decision of last November reversing the conviction of Mrs Ada Martin, alleged head of a loop abortion syndicate, and Mrs Josephine Kuder, her receptionist (THE JOURNAL, Aug 22, 1942, p 1435).

New Director of Health Education—Rachel E Spinney, M S P H, has been appointed director of health education for the Tuberculosis Institute of Chicago and Cook County to succeed Alice H Miller, C P H, who has become health education consultant with the U S Public Health Service, at Kingston, Lenoir County, N C. Miss Spinney has recently been health education secretary of the Hartford Tuberculosis and Public Health Society in Connecticut. She received her master's degree in public health at the University of Michigan, Ann Arbor.

INDIANA

Course in Otolaryngology—The Indiana University School of Medicine Indianapolis will conduct its annual anatomic and clinical course in otolaryngology April 12-24, consisting primarily of studies of the anatomy of the head and neck. Morning periods will be devoted to correlated subjects in otolaryngology, discussions and clinics, while the afternoon and evening sessions will be devoted to anatomic dissections and presentations. On Sunday evening April 11, the Indianapolis Academy of Ophthalmology and Otolaryngology will give a dinner at the Indianapolis Athletic Club.

KANSAS

New Director of Venereal Disease—Dr Regnar M Sorensen, surgeon, U S Public Health Service Reserve, formerly of Des Moines, has been detailed by the service as director of the division of venereal diseases of the state board of health. He succeeded Dr Robert H Riedel, Topeka, who has been given a leave to serve as captain in the medical corps of the U S Army.

Lectures on Psychoanalysis—The Topeka Institute for Psychoanalysis which operates in three branches at Topeka, Los Angeles and San Francisco recently had as guest lecturers in its Topeka branch Dr Alan Gregg, New York, director for the medical sciences, Rockefeller Foundation on "Medical Communications." Dr Frank Fremont-Smith, New York, director of the medical division Josiah Macy Jr Foundation, "Trends in Medical Research." Norman R F Maier, Ph D, University of Michigan, Ann Arbor, "Abnormal Fixation as a Form of Compulsion in the Behavior of Rats" and "Direction of Selective Mechanisms in Thinking" and Robert R Sears, Ph D, Iowa Child Welfare Research Institute, Iowa University, Iowa City, "Psychological Research." Seminars and lectures are also presented at the Los Angeles and San Francisco branches. Additional information on Topeka training activities may be obtained from Dr Ernest Lewy, 3617 West Sixth Avenue, Topeka, and on California training activities from Dr Ernst Simmel, 555 N Wilcox Avenue, Los Angeles.

KENTUCKY

Portrait of Dr Barbour—An oil painting of Dr Philip F Barbour, Louisville, has been presented to the University of Louisville School of Medicine by senior medical students, honoring the physician's many years' service to the school. Dr Barbour, who is now pediatric consultant to the state department of health, was clinical professor of diseases of children and head of the department of pediatrics at the medical school from 1908 to 1940. He was president of the state medical society in 1932.

MASSACHUSETTS

Postgraduate Course of College of Physicians—The American College of Physicians is sponsoring a course on internal medicine at Boston University School of Medicine and Massachusetts Memorial Hospitals, Boston, April 5-10. The course is similar to those conducted in January and February at the University of Minnesota Medical School, Minneapolis, and the Mayo Clinic, Rochester, Minn.

MICHIGAN

Training Program for Physicians in Industry—A program has been formulated in Michigan for the training of physicians for replacements in industry. Consisting of three weeks' study, the work is part of a plan whereby the state committees on procurement and assignment and on industrial health may assist industry in solving the medical procurement problems of industry. The first week's work will cover preventive aspects, the second field work and the third observation of working methods in full time medical departments. No charge is made for instruction but physicians will pay their own living expenses. The training will be given by the bureau of industrial hygiene of the state department of health. A similar program was launched in Indiana recently (*THE JOURNAL*, February 13, p 531).

MISSISSIPPI

Personal—Dr Clyde M Speck, medical superintendent of the Mississippi State Hospital, Whitfield, has been appointed associate professor of psychiatry at the University of Mississippi School of Medicine, University.

Society News—Dr Hilliard E Miller, New Orleans, was asked to repeat the annual C Jeff Miller address of the Southeastern Surgical Congress before the Central Mississippi Medical Society in Jackson recently. Dr Miller had delivered the lecture before the Southeastern Congress in March, but because his brother, the late Dr C. Jeff Miller, was well known to the Mississippi group, the lecture was made a feature of a recent meeting.

Lectures on Venereal Diseases—On March 2 Dr Percy S Pelouze, assistant professor of urology at the University of Pennsylvania School of Medicine, Philadelphia, and consultant for the gonorrhea control program for the U S Public Health Service, opened a series of lectures on the diagnosis and treatment of gonorrhea at regular and special meetings of medical societies throughout the state. He spoke in Jackson March 2, Vicksburg March 3, Greenwood March 4, Greenville March 5, Tupelo March 9, Clarksdale March 10, Laurel March 11, Oxford March 12, Natchez March 16, McComb March 17, Meridian March 18, Jackson March 20 and Biloxi March 24.

Special Examinations for License to Practice—The Mississippi State Board of Health announces that special examinations for license to practice medicine will be held at the Robert E. Lee Hotel, Jackson, April 7-8. The Mississippi law permits examinations to second year students on the first two years of medicine as well as all the examinations for four year men. At this special examination applicants will be accepted who still lack a few weeks of finishing the first two years or finishing the four years in medicine, but results of such examinations will become effective only after successful completion of the courses concerned. The regular examinations will be postponed until some time in September.

MISSOURI

Program on Industrial Health—"What Should Be Done to Improve the Health Program and the Medical Care of the Worker" was the theme of a program in Kansas City, March 17, the first symposium in a series on industrial health planned for the greater Kansas City area. Representatives of labor management, public health, industrial nurses, industrial physicians and the compensation board participated in the program. Dr Clarence D Selby, medical director of General Motors Corporation, Detroit, was the guest speaker. Local health agencies cooperated in presenting the project.

NEW YORK

Doctors' War Fund—The recent establishment of a Doctors' War Fund, maintained by the physicians of Huntington Township, has been announced. The purpose of the fund is to provide regular financial assistance of \$100 monthly to families of those men who have gone into service. Trustees of the fund, which is to be given a year's trial, are Drs Neil E Falkenburg, Huntington; Joseph G Patiky, Huntington; and Wilbur C Travis, Northport. It is hoped that through the plan an adjustment can be made between the civilian income and that of an army officer, according to the state medical journal.

Cancer Teaching Day—A special program will be presented at the Rochester Academy of Medicine, April 15, to constitute a "cancer teaching day," under the auspices of the Medical Society of the County of Monroe, Seventh District Branch of the state medical society, the academy of medicine, the University of Rochester School of Medicine and Dentistry, Tumor Clinic Association of the State of New York, the state medical society and the state division of cancer control. The speakers will include Drs Norman Treves, New York, "Care of the Advanced Cancer Patient" and Fred W Stewart, New York, "What May Be Logically Expected from Preoperative and Postoperative Radiation in Mammary Cancer." At an evening session Drs Cornelius P Rhoads, New York, will discuss "Role of the Endocrines in Neoplastic Disease" and Charles B Huggins, Chicago, "Diagnosis and Treatment of Prostatic Cancer."

Minimum Medical Standards in Industry—The Buffalo District Committee for Industrial Health, of which Dr Herbert H Bauckus, Buffalo, is chairman, has drawn up minimum medical standards for use in industry. The recommendations, which have been sent to all plants in the Buffalo area, are designed to meet low cost health improvements in various plants differing in size and accommodations. The recommendations emphasize the need for good sanitary facilities as a prerequisite to prevent the spread of communicable and occupational diseases, the value of preventive vaccinations, the prevention and care of colds and need for selection in foods. A meeting of the study committee for industrial health of the Medical Society of the State of New York was held in Buffalo recently to discuss plans for a more accelerated promotion of industrial health committees similar to the one set up in Buffalo. Cities tentatively considered for proposed committees were Rochester, Syracuse, Utica and Schenectady.

Child Care Plan Approved—The state war council has approved a \$15,000,000 program for the care of children of women working in war industry, one third of the cost to be borne by the state. The *New York Times* reported on March 12. The state's share of the cost will become available on April 1 from the \$7,500,000 provided by Governor Dewey in his executive budget for child care equipment reserve pay increases for the state police and other purposes. The other two thirds of the cost will be divided evenly between the localities and parents making use of the centers. Use of child care centers will be available to all children living in the state whose mothers are working either in war industries or in manpower shortage areas. Applications for state aid will be filed by local war councils but may be made on behalf of religious, charitable, fraternal or community groups seeking to establish child care centers. Child care projects to be conducted in the public schools will be investigated, passed on and supervised by the state education department, but all other such centers will come under the jurisdiction of the social welfare department. The War Council in approving the plan prepared by Governor Dewey's staff, adopted several resolutions of general policy, one of which states that child care centers will be established only in areas where a manpower shortage exists or where mothers are working in the production of goods needed by United Nations forces for the war. The sole exception to the general rules laid down for operation of the program was made to preserve twenty-eight settlement house nursery schools in Manhattan. These institutions, which previously have been used by working mothers whether in war industry or not, will lose on April 1 the Works Project Administration grants which have maintained them. The War Council has agreed to help support these child care centers on the same basis as others to be established provided they make full use of existing facilities to care for children of mothers in war industry. The cost of child care under the program is estimated at a maximum of \$275 a year for each child between 2 and 5 years of age and \$100 a year for children over 5 who presumably attend day school several hours a day. The centers would be open sixty-five to seventy hours a week and then only during the day.

New York City

Courses in Cardiovascular Diseases and Gastroenterology—Mount Sinai Hospital announces two twelve weeks' postgraduate courses, one in cardiovascular diseases the other in gastroenterology April 5-June 23. The former course has been designed to deal with the broader diagnostic and therapeutic aspects of the more common clinical patterns of rheumatic, arteriosclerotic, syphilitic and congenital heart diseases while the course in gastroenterology will attempt to cover the fundamentals of diagnosis, clinical medicine and therapy with particular emphasis on medical symptomatology. Additional information may be obtained from the Secretary for Medical Instruction Mount Sinai Hospital, Fifth Avenue and 100th Street.

Committee Recommends Oleomargarine—The committee on public relations of the New York Academy of Medicine recommended on February 14 that oleomargarine be made more freely available to the public as a butter substitute and urged that federal and state laws restricting the manufacture and distribution of oleomargarine be suspended for the duration of the war. Specifically, the committee suggested that the federal government make it mandatory for all oleomargarine to be fortified with vitamin A at a uniform level of 9,000 units per pound, according to the New York *Herald Tribune*. Charging that there had been much misinformation about oleomargarine, the committee is reported to have said that "under the standards set up by the Food and Drug Administration oleomargarine is as clean and sanitary a food as butter."

New Blood Exchange Bank—A blood and plasma exchange bank has been established under the auspices of the Medical Society of the County of New York with the approval of the Greater New York Hospital Association. The exchange is a nonprofit organization and has a membership of thirty-five hospitals. Its executive personnel serves without compensation. Overhead costs are borne by blood supplying hospitals. The exchange bank is managed by eight administrators and the eight transfusionists of the supplying hospitals. According to the New York *Times*, in a six month preliminary test involving only three institutions, one hundred transfusions were carried out with an estimated saving of approximately \$1,900 to patients and hospitals. The *Times* pointed out that the next step is to extend the plan to counties that border New York, with the ultimate establishment of a national organization. In the case of a needed transfusion members of the patient's family offer their blood, formerly, if the blood did not match, the donors were rejected. Now two whose blood is of no value to the patient can go to the blood and plasma bank, each giving a pint of blood. If only one donor gives blood to the exchange bank \$10 is charged. If the patient prefers not to send donors but to pay for blood the cost is \$20. The hospital that receives the blood makes its own charge for laboratory and operating room services. Thus eight large hospitals with blood banks (called supplying hospitals) are interlaced with hospitals without banks (called requisitioning hospitals).

OHIO

Children's Dental Health Day—The *Bulletin* of the Academy of Medicine of Cleveland reports that a movement is under way to hold a national observance of Children's Dental Health Day, an expansion of the local observance, February 1, sponsored by the Cleveland Dental Society. The dental society approved a resolution recommending that the first of February each year be designated a national dental health day for submission to the Ohio State Dental Society and the American Dental Association.

In Memory of Dr Crile—Special memorial services were held recently in Amasa Stone Chapel of Western Reserve University, Cleveland for Dr George W Crile who died on January 7. The speakers included Brig Gen Fred W Rankin Lexington Ky M C U S Army President of the American Medical Association, Dr Irvin Abell, Louisville Ky president of the American College of Surgeons, William S Wickenden, LL.D. president of the Case School of Applied Science and a director of the Cleveland Clinic Foundation, of which Dr Crile was a co-founder and Winfred G Leutner LL.D. president of Western Reserve University.

Dr Leggo Directs Industrial Hygiene Service—Ralph Christopher Leggo, surgeon U S Public Health Service Reserve has been placed in charge of the industrial hygiene service of the state department of health. A former secretary of the Western Association of Industrial Physicians and Surgeons and associate editor of *Industrial Medicine* Dr Leggo recently was industrial hygiene physician for the Missouri State

Board of Health at Jefferson City. He once served as consultant in occupational hygiene to the California State Department of Health and as plant physician for the California and Hawaiian Sugar Refining Corporation. In compliance with the recommendations of the newly organized committee on industrial health of the state medical association, local groups are being formed and plans are under way to present refresher courses throughout the state, specialized programs to be announced later.

PENNSYLVANIA

State Health Commissioner Reappointed—Dr Alexander H Stewart, Harrisburg has been reappointed secretary of the state board of health by Gen Edward Martin, Harrisburg, the new governor of Pennsylvania.

Philadelphia

Annual Health Institute—The woman's auxiliary of the Philadelphia County Medical Society will conduct its thirteenth annual health institute in the society's auditorium on April 13. "Our Own Health" will be the theme of the program, which includes the following speakers all of Philadelphia:

Dr Truman G Schnabel Is It Kidney?
Dr Walter L Cariss What's in a Cold?
Dr Merle M Miller, Influence of Allergy on Our Health.
Dr George M Laws, How We Clunge with the Times
Dr Herbert T Kelly Our Changing Foods
Dr George C Griffith Care of the Heart—Normal and Abnormal

Dr William Bates, president of the county medical society will deliver the address of welcome.

TEXAS

Physicians Respond to Placement in Industry—The committee on industrial health of the state medical association announces that ninety-one physicians have been placed in either full or part time positions in various industrial plants throughout the state. Thus far the Texas committee leads in the movement to have the state committees on industrial health serve as a clearing house for the placement of physicians in industry.

UTAH

Activities at Utah Medical School—Recent appointments to the University of Utah School of Medicine, Salt Lake City include those of Dr Emil G Holmstrom instructor in obstetrics and gynecology, University of Minnesota School of Medicine, Minneapolis to assistant professor of obstetrics and gynecology. Dr Robert H Alway, instructor in pediatrics at Minnesota, to a similar position at Utah and Louis P Gehhardt Jr, Ph.D., formerly assistant professor of bacteriology at Stanford University School of Medicine San Francisco, to associate professor of bacteriology. Dr John A Anderson associate professor of pediatrics at Minnesota, has been appointed professor and head of the department of pediatrics. Under the recent reorganization the two year university medical school has been expanded to a four year classification. The classes will be limited to forty students each in the last two years. A working agreement has been drawn up between the regents of the university and the commissioners of Salt Lake County, giving the university complete control of all clinical material at Salt Lake County General Hospital by empowering the medical school to nominate members of the staff. This hospital of over 250 beds, plus clinical material available at the Dr W H Groves Latter-Day Saints Hospital, the Holy Cross Hospital, the Veterans Administration Facility and St Marks Hospital, all in Salt Lake City will give the medical school ample clinical material for teaching purposes.

WEST VIRGINIA

New Division of Cancer Control—A new division of cancer control will be set up in the state health department under the provisions of a bill (S B 36) passed by the house of delegates of West Virginia and sent to the governor March 12. The senate had previously passed the bill without a dissenting vote. The new division will be under the supervision of the state health commissioner, the head of the division to be appointed by the commissioner in consultation with the public health council. Besides providing for a wide educational program stressing the importance of early diagnosis the bill, which was sponsored by the state medical association, provides for the establishment of cancer diagnostic and treatment clinics in general hospitals of the state meeting minimum requirements prescribed by the division in consultation with the West Virginia State Medical Association. Treatment will be furnished needy patients within the limits of available funds. The budget bill passed March 13 appropriates \$50,000 annually for the treatment and control of cancer.

GENERAL

Easter Seals for Crippled Children—The tenth annual sale of Easter seals for crippled children, sponsored by the National Society for Crippled Children and its affiliated organizations, opened March 26 to continue to April 5.

Meetings Canceled—The Pacific Coast Oto-Ophthalmological Society has canceled its 1943 meeting—The executive committee of the American Diabetes Association has canceled the third annual meeting of the association—Announcement is made of the cancellation of the 1943 meeting of the Central Neuropsychiatric Association.

Activities of Hospital Association—The board of trustees of the American Hospital Association, at its meeting in Chicago, February 13, voted to hold its annual meeting, the place and time to be announced later. The appointment of a committee was also authorized to study the publication of a hospital magazine and to consider the employment of an editor. Approval was also given to the employment of a new librarian as soon after July 1 as possible. The board of trustees gave their annual banquet to the presidents and secretaries as a testimonial dinner to Asa S. Bacon, superintendent emeritus of Presbyterian Hospital of Chicago, a past president of the American Hospital Association and for thirty-five years its treasurer and to Dr. Bert W. Caldwell, executive secretary emeritus and editor of *Hospitals*. Silver plaques were presented to Mr. Bacon and to Dr. Caldwell.

New Medical Director of Industrial Hygiene Foundation—Dr. Charles F. Kutscher, Pittsburgh, a member of the industrial health and hygiene committee of the Allegheny County Medical Society, has been named medical adviser of Industrial Hygiene Foundation of America. He succeeds Dr. Samuel R. Haythorn, Pittsburgh, president of the county medical society who has been medical adviser of the organization since it was first established in 1935 as the Air Hygiene Foundation of America. Dr. Haythorn has been advanced to medical consultant. Dr. Kutscher graduated at the University of Pittsburgh School of Medicine in 1927. Wesley C. L. Hemen, formerly of the industrial hygiene division of the Massachusetts Department of Labor, Boston, has become industrial hygiene engineer at the foundation.

Resolution About a Commission to Study Hospitals—At a meeting in New York, February 25, a resolution was adopted by the Hospital Bureau of Standards and Supplies urging the appointment by the President of the United States of a commission 'to study the problem of the most efficient use of the country's hospitals in connection with the war; this commission to consist of representatives active in the management of voluntary, public, and governmental hospitals and national health agencies, with authority to secure adequate professional assistance to advise the commission in regard to technical matters arising in connection with the study. The Bureau of Hospital Standards also adopted a resolution signifying its cooperation with all government agencies working on the problem of the simplification and standardization of hospital goods to the end that wastage of materials and man hours be reduced.

Association of Industrial Physicians and Surgeons—The annual convention of the Western Association of Industrial Physicians and Surgeons will be held at the Biltmore Hotel in Los Angeles, April 29-May 1, under the presidency of Dr. Benjamin J. Grees. Los Angeles. Among the speakers will be:

Dr. William A. Sawyer, medical director of the Eastman Kodak Company, Rochester, N. Y. (subject not announced)
Philip Drinker, Ch. E., professor of industrial hygiene, Harvard School of Public Health, Boston (subject not announced)
Dr. John H. Foulger, director of the Haskell Laboratories of Industrial Toxicology, Wilmington, Del. (subject not announced)
Lyman D. Hencock, dental surgeon, U. S. Public Health Service, Bethesda, Md. (Dentistry's Place in Industry)
Dr. Clifford Kuh, director of the Bureau of Industrial Health, California State Department of Health, Sacramento (Rehabilitation of the War Wounded into Industry)
Mr. Robert Stormont, Lockheed Aircraft Corporation, Burbank (Rehabilitation of the War Wounded into Industry)
Lieut. Comdr. Robert S. Poos, surgeon, U. S. Navy, Washington, D. C. (subject not announced)

Additional information may be obtained from the secretary, Dr. Rutherford T. Johnstone, director, department of occupational diseases, Golden State Hospital, Los Angeles.

Report of Georgia Warm Springs Foundation—During the fiscal year ended September 1942, 571 patients received treatment at the Georgia Warm Springs Foundation, and of these 390 or 68.3 per cent required partial or full financial aid. The average daily number of patients in residence

throughout the year was 101.16 and they received 36,917 hospital days' care. In the previous year 437 patients were treated for a total of 32,590 hospital days' care. A therapeutic pool completed in June 1942, is the newest addition to the facilities at the foundation. The physical therapy postgraduate school initiated its formal course of instruction in July 1941. The course lasts twelve consecutive months and is open only to technicians who have been graduated from schools of physical therapy approved by the Council on Medical Education and Hospitals of the American Medical Association. The foundation reported a gross revenue for the fiscal year of \$263,991.98 and expenditures totaling \$450,803.75, leaving a deficit of \$186,812. The deficit, however, was covered by a grant of \$262,727 from the National Foundation for Infantile Paralysis. The difference of \$75,915 was added to the reserve fund, which now stands at \$1,824,834.

LATIN AMERICA

Congress on Endocrinology Postponed—The third Pan American Congress of Endocrinology, which was to be held in Buenos Aires, July 1-6, has been postponed.

Congress on Neurology and Legal Medicine—Plans are under way to hold the first congress of the Latin American Academy of Neurology, Psychiatry and Legal Medicine; the dates to be announced later.

New Department of Nutrition in Paraguay—*Scimada Medica* recently announced the formation of a department of nutrition in the ministry of public health of the republic of Paraguay. The unit was formed under the direction of Dr. Francisco A. Montaldo, who for two years specialized in the study of nutrition at the Institute of Nutrition at Buenos Aires on a scholarship of the government of Paraguay.

New Publications—The *Anales de la Catidia de Clinica Ginecologica* recently made its appearance. The first issue is dated July 1942 and serves to commemorate the twentieth anniversary of the department of gynecology of the faculty of medical sciences of the National University of Rosario, Argentina. Dr. Rafael Araya is the editor. The Academy of the History of Medicine at the University of Buenos Aires began the publication of the *Revista Argentina de Historia de la Medicina*. Prof. Juan Ramon Beltran is founder and editor of the new journal, which is to appear every four months. The issues of January and May 1942, which were recently received, contain original articles, notes and reviews of books and articles. Works to be reviewed should be submitted in duplicate to Professor Beltran, Echeverria 1606, Buenos Aires. The first issue of *Pediatría de las Américas* made its appearance with the January 1943 issue. Dr. Alfonso G. Alarcon is the editor. The headquarters of the new journal, which will be published monthly, are Ponciano Arraga 6, Despacho 2, Mexico, D. F.

FOREIGN

X-Ray Pioneer Dies—Harold J. Suggars, the last of four English x-ray pioneers, died March 9 at the age of 65 in Bellerica, Essex. According to the *New York Times*, forty-one years ago Mr. Suggars, a carpenter, volunteered to assist Dr. Ernest H. Harnack. Two other associates, Reginald Blackwell and E. E. Wilson, also died with aggravated burn conditions.

Physician Honored—King George VI recently conferred a peerage on Sir Charles McMoran Wilson, president of the Royal College of Physicians of London and personal physician to Winston Churchill, prime minister. Sir Charles has accompanied Mr. Churchill on at least three 'far distant illud capitals on missions of great consequence to the united war effort' the *British Medical Journal* reports.

Sir Farquhar Buzzard to Retire as Regius Professor—Sir Edward Farquhar Buzzard will retire in April from the regius professorship of medicine at the University of Oxford, Oxford City, a position he has occupied since 1928. Plans are under way to establish a Buzzard scholarship or prize in medicine and to present a portrait to the school in his honor. Sir Farquhar was president of the British Medical Association 1936-1937 and a representative of the General Medical Council 1929-1939.

Deaths in Other Countries

Dr. Russell Henry Jocelyn Swan, London, emeritus surgeon to the Royal Cancer Hospital and house surgeon at Guy's Hospital and St. Peter's Hospital for Stone, widely known for his work on cancer, died March 6, aged 66. Dr. Swan was also surgeon of the Royal Air Force Hospital and the American Red Cross Hospital for Officers.

The Starvation of Children in Occupied Countries

The plight of the civil population in enemy occupied Europe causes much concern. There is serious want, and many have died from starvation. Plans have been made for immediate relief when hostilities cease. The condition of the children has given rise to letters in the *Times* from representative persons. Dr L G Parsons, president of the British Pediatric Association and Dr Reginald Lightwood, secretary of the Child Relief Subcommittee, draw a harrowing picture. An eye witness has described the children in Athens as "without strength to beg." One child said "I have lost my mother—she died of hunger, my brother died last night because we had not eaten anything for four days." The Athens Welfare Service reports that 9 out of 10 children die before they reach the age of 6 months. An arrangement was made to relax the blockade and allow 100 tons of dried Canadian milk to be imported monthly, a bare pittance for a child population of 2,000,000. Under an earlier plan, suggested by Sweden, 15,000 tons of wheat has been sent monthly since August, but cereal without milk and vitamins is deficient and increases rickets. A famine relief committee is supported by the archbishop of Canterbury and the cardinal archbishop of Westminster in a plea to the British government to send enough dried milk and vitamins to maintain the lives of children under 16 and of expectant and nursing mothers in Greece and Belgium. Each country requires about 2,000 tons monthly. The International Red Cross gives guarantees against the food being used by the enemy.

In another letter to the *Times* H E Kershner, director of relief, American Friends Service Committee, states that close study of the continent convinces him that in order to shorten the war and make reconstruction less difficult we should save what we can of the children left in the occupied countries. He has seen the weights of the newborn fall to almost half normal and infant mortality climb to thrice normal. He has seen the children of southern France practically stop growing and a large percentage lose weight. Many lost their memory and learned nothing in school. Many are kept in bed to conserve their strength. For lack of clothing, some go to school only on warm days or on alternate days, using one another's clothing.

In a third letter to the *Times* Lord Noel-Buxton, president, and other officials of the "Save the Children Fund" endorse the previous letters. They have just completed an inquiry into the condition of children in the occupied countries and found starvation to be even more widespread and more terrible than the preceding writers state, perhaps in the desire to avoid exaggeration. In no country under enemy domination is food sufficient to maintain the children in health, in many it is insufficient to keep them alive. Even in countries normally self sufficient in basic foodstuffs, such as the Netherlands and Norway, requisition of the country's produce, by means either overt or covert, has debased the standard of living, threatening the young, while in Poland and Yugoslavia one must ask how many children will be left alive after another year of war.

Medical Students Confer

The formation of the British Medical Students Association was reported in a previous letter. The inaugural meeting was held last June. A congress of the association has been held at the British Medical Association House, at which nearly all the medical schools in the country were represented. At the opening session Mr Ernest Brown, minister of health, delivered an address in which he reviewed the position of students

under the National Service Act. The reservation of male students was subject to periodic certification, satisfactory progress in their studies and performance of part time national service.

Subsequent sessions were devoted to a memorandum on education which had been prepared by a subcommittee. Among the points in the debate were the wider use of municipal hospitals for teaching, the benefits of a system of apprenticeship to general practitioners, the abolition of the long vacation and introducing a fourth term. One student complained that while the report mentioned sociology as a premedical subject it did not recommend an examination in this subject. Without that little interest would be taken in it. Another wanted a more prominent place in the curriculum for industrial medicine. There was much debate on the admission of women. One student was strongly against coeducation in the medical schools, but the general feeling favored it. Many men as well as women students urged that women should be admitted to the profession on exactly the same basis as men.

Prof J A Ryle, honorary president of the association, gave the closing address. He declared that the training and practice of the profession had been too individualistic. It had been directed too much to the intimate as opposed to the ultimate aspect of disease—to the tubercle bacillus rather than to the conditions under which tuberculosis thrived. There had been too much separation of general practitioners from one another, of consultants from general practitioners, of hospital from domiciliary service, of public health service from general practice, of research from all the rest. The student was taught little about the subject of health but much about departures from it.

Vital Statistics Improve Notwithstanding the War

A total of 168,638 live births in England and Wales during the September quarter was the highest in any quarter since June 1930. In comparison with previous third quarters it was the highest since 1926 and represented a birth rate of 161 per thousand of population, the highest since 1930. In the quarter 86,893 boys and 81,745 girls were born, a proportion of 1,063 to 1,000, compared with an average of 1,052 to 1,000 for the ten preceding third quarters. Stillbirths numbered 5,425, or 31 per cent of the total births, the lowest percentage yet recorded.

For the first time in any quarter since 1936 the total number of deaths fell below 100,000. The figure was 97,276, which represents an annual death rate of 93 per thousand and was lower than that of any third quarter since 1927. It compares with 97 for the third quarter of 1941 and an average of 10 for the same quarters of the previous five years. There were 6,766 deaths of infants under 1 year, a rate of 40 per thousand live births. This was 5 below the average of the ten preceding third quarters and was equal to the low record that was reached in 1939.

There was a decline in the number of marriages. The total for the quarter of 95,713 was 8,620 fewer than in the corresponding quarter of 1941 and 31,937 below the average for the same quarters of the previous five years. The marriage rate of 183 per thousand of population was lower than that of any third quarter since 1936. The explanation of the decline seems to be as follows. The outbreak of war was followed by an increase in the number of marriages, which is now reflected in the rise in the birth rate. This was partly due to the fact that in addition to their ordinary pay soldiers receive allowances for wives and children. The increase in the number of marriages was largely due to earlier ones, thus diminishing those which would take place in the ordinary course in the later years of the war.

Pneumoconiosis Made an Industrial Disease

In the House of Commons a workmen's compensation bill making pneumoconiosis an industrial disease was read a second time. The disease is due to the inhalation of dust in coal mines and elsewhere. Compensation will be paid for any form, including old cases in men who have left the industry. It is proposed to pay those affected \$4 a week in addition to their national health insurance grant in the case of temporary incapacity and \$1,000 to widows in case of death. The cost will be levied on the output of coal. It is estimated that it would not exceed 2 cents per ton, and that only for a single year.

JERUSALEM, PALESTINE

(From Our Regular Correspondent)

Jan 15, 1943

Microbiological Society of Palestine

On Dec 9, 1942 the fifth annual meeting of the Microbiological Society of Palestine was held under the chairmanship of Dr Olitzki in the premises of the Medical School of the Hebrew University.

In his opening address, Olitzki pointed out that in this country too microbiologic studies, originally concerned only with pure research problems, have been transferred to the sphere of practical work by war conditions (preparation of serums and vaccines, army hygiene, diagnostic courses of tropical and subtropical diseases, antimalaria measures).

In the theoretical part of the meeting Ernst Simon of Rehovoth gave a survey on "New Ways in the Investigation of Bacterial Metabolism" wherein he outlined the progress marked by the introduction of the electron microscope, spectography and the ultra centrifuge in the investigation of bacterial metabolism and in virus research.

Subjects referring to war conditions were dealt with by Olenik, who gave an outline of the method used at the bacteriologic department of the Hebrew University for the preparation of antityphus vaccine, and further by Ashbel, who reported on "Immunologic Properties of Spirochaeta Recurrentis of Cases from the Libyan Desert." Dealing with practical issues, Rappaport discussed the possibility of replacing peptone or bouillon in the culture medium by fish extracts.

Subjects especially concerning this country were discussed by Tshernomoretz speaking on the "successful immunization of cattle against Theileria infection," by Salternik who reported on the identification of the various anopheles species by the pattern in which their eggs are arranged on the water surface, and by B Levy on the preparation of highly active antianthrax vaccine. Volcani reported on the microflora of the bottom layer of the Dead Sea, where he had found various species of living protozoa and bacteria.

Guggenheim gave an account of his experiments carried out with a view to determine the reduced resistance of vitamin A deficient rats to typhus muris infection. Olitzki spoke about the method used in the preparation of highly virulent dysentery toxins (Shiga) from strains grown on synthetic culture mediums.

Diagnostic problems were dealt with by Adler ("On the Culture of Trichomonas hominis Without Bacterial Contamination") Klopstock discussed the value of the amebic complement reaction, while Gurewitz reported on skin tests in bacillary dysentery.

Pharmacologic Institute for Mount Scopus

With the establishment of a pharmacologic institute under the joint auspices of the Rothschild Hadassah Hospital and the Hebrew University another step has been taken toward the realization of a medical faculty on Mount Scopus. The institute is housed in the Ratnoff building of the Medical Center.

The head of the institute is Prof G Wertheimer, who holds at present also the chair of physiologic chemistry at the Hebrew University. Professor Wertheimer has for a long time worked together with Professor Abderhalden at Halle.

The New Haifa Hadassah Hospital

Sir Harold McMichael, high commissioner of Palestine, opened the new Hadassah Rothschild Hospital of the Jewish Community in Haifa on Oct 26, 1942. The hospital, on a 14 donum site off Keith Roach Avenue between Mount Carmel and Hadar Hacarmel, was built at a cost of £25,000. The sum came from the Jewish emergency tax, the Haifa Jewish Community, the Hadassah organization and P I C A funds and the government. The hospital has at present 60 beds in three sections (surgical, women and children). In emergencies the bed capacity can be doubled. The final project is the expansion to 200 beds. The director of the hospital is Dr S Seide, an internist. The hospital had already proved its value during the recent outbreak of typhoid.

Formation of a French Medical Association

A Palestine branch of the Association for French Medical Science in the Middle East was established on Oct 22 1942 under the auspices of General Catroux, Fighting French national commissioner and Surgeon General Guirree, director of health services to the Fighting French forces in the Levant. The aim of the association includes the fostering of contacts among the many physicians with French training now in the Middle East. On the first meeting in Jerusalem two papers were read one by Dr Champenois, director of the French Hospital in Bethlehem, the other by Dr Bauer, head of the French Hospital in Jerusalem.

Polish Doctors Meeting in Tel-Aviv

A conference of Polish military and refugee physicians took place on Oct 7, 1942 at the Strauss Health Center, Tel-Aviv. The main theme was the treatment of Mediterranean diseases liable to be carried back to Poland by soldiers and refugees in the Near East. The conference was opened by Dr A Wolynski and Prof A Laskiewicz. Papers were read by Prof A Mandel, Professor Dvobowski, Professor Marcus and others.

Marriages

JAMES ALLAN FIELDS Sanford Fla to Miss Mona Jean Carpenter of Johnson City, Tenn in Clearwater, Fla, in February.

LUKE W QUERY JR, Charlotte N C, to Miss Margaret Newton of Birmingham, Ala, in Fort McPherson, Ga, February 8.

WILLIAM LUTKINS JOHNSTON Birmingham Ala, to Miss Margaret Louise Richards of Glasgow, Pa, February 23.

ROSCOE L PULLEN New Orleans, to Miss Gwendolen Williams of Lethbridge, Alta, Canada, December 12.

SAMUEL SPRIGG JACOB III, Bethany W Va, to Miss Mary Ellen Bibbee of Athens Ohio December 19.

BEVERLY CAROLINE PAYNE JR, Beaumont, Texas, to Miss Elizabeth Mason of Baytown February 7.

ROBERT McCUE HALL Raleigh, N C, to Dr JULIA ROWENA SIDBURY of Wilmington, February 27.

JOHN W R THOMA Springfield, Ill, to Miss Kathleen Wiggin in St Louis in February.

JOHN A SCHILLING New York to Miss Barbara Whipple of Rochester, N Y February 13.

LLOYD DAVIS MILLER to Miss Jane Evelyn Hartsell, both of Raleigh, N C, February 13.

EDWARD F HARDMAN, Youngstown, Ohio, to Miss Ann Russ in Baltimore, March 6.

SIDNEY C KEYES, Youngstown, Ohio, to Miss Alma Toepfner, February 6.

Deaths

John Franklin Dufferin Cook * Pierre, S. D., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897, member of the House of Delegates of the American Medical Association in 1920, 1930 and 1932, superintendent of the State Board of Health and of medical licensure, secretary-treasurer of the South Dakota State Medical Association from 1925 to 1937 and in 1938 president, served as president of the Northwest Regional Conference captain in the medical reserve corps of the U. S. Army not on active duty, served with the same rank in the medical corps of the U. S. Army during World War I and as president of the medical advisory board for the counties of Day and Marshall, also as county coroner and as a member of the Marshall County Board of Health fellow of the American College of Surgeons, member of the staff of the Peabody Hospital, Webster, member of the associate staff of St. Luke's Hospital, Aberdeen member of the board of directors of the *Journal-Lancet*, aged 70, died, January 27 in St. Mary's Hospital following a prostatic resection.

Carl B. Wagner * Chicago, Illinois Medical College, Chicago 1909, honorary life member of the American Academy of Ophthalmology and Otolaryngology, member of the American Association for the Advancement of Science, Chicago Ophthalmological Society and the International Congress of Ophthalmology, formerly clinical professor of ophthalmology at the Loyola University School of Medicine, member of the consulting staff of the Cook County Hospital served on the staff of the Chicago Eye, Ear, Nose and Throat Hospital, aged 66, died February 1, in the Illinois Masonic Hospital of carcinoma of the prostate.

Joseph Francis Wallace, Silver Spring Md., Georgetown University School of Medicine, Washington, D. C., 1899, at one time attending physician at St. Vincent's Orphan Asylum, police surgeon and secretary of the board of health in Leavenworth Kan. at one time surgeon in the U. S. Public Health Service Reserve and the Veterans Administration, formerly manager and chief of the tuberculosis service of the Veterans Administration Facility at Castle Point, N. Y. served during World War I, aged 68, died February 11, of coronary occlusion.

Edward Adams, New York, Cornell University Medical College New York 1899, member of the Medical Society of the State of New York, served during World War I, lieutenant colonel in the medical reserve corps of the U. S. Army not on active duty, aged 65, died, February 7, of heart disease.

John Jeremiah Ahern, Oldham S. D., Physio Medical College of Indiana Indianapolis, 1896, Rush Medical College Chicago 1897, aged 75, died, January 14, in the Volga (S. D.) Hospital.

George Beal Arnold, Cincinnati Medical College of Ohio Cincinnati, 1896, aged 69, died, December 25, of coronary embolism.

William Edwin Boozan * Elizabeth N. J. University and Bellevue Hospital Medical College, New York, 1909, fellow of the American College of Surgeons, aged 64, on the staff of the Alexian Brothers Hospital, served as chief of staff and chief of the eye, ear, nose and throat department of St. Elizabeth's Hospital, where he died, February 5, of coronary occlusion.

Charles Harvey Boyer, Easton, Pa., Jefferson Medical College of Philadelphia, 1894, member of the Medical Society of the State of Pennsylvania, aged 73, died, January 13.

Marcus Carter, Burlington Junction Mo., Kentucky School of Medicine, Louisville, 1877, also a druggist, aged 88, died January 31, of pulmonary embolus and a fractured hip received in a fall.

Thomas J. Casto, Charleston, W. Va., Maryland Medical College, Baltimore, 1902, member of the West Virginia State Medical Association, aged 71, for many years on the staff of the Mountain State Memorial Hospital, where he died, January 20, of cirrhosis of the liver and diabetes mellitus.

Franklin T. Chamberlin, Aquia, Va., Georgetown University School of Medicine, Washington, D. C., 1885, U. S. Army Medical School, Washington, D. C., 1924, aged 79, died, February 3.

Thomas Kennerly Conrad, Chevy Chase, Md., Georgetown University School of Medicine, Washington D. C., 1908, member of the Medical and Surgical Faculty of Maryland, major in the medical reserve corps of the U. S. Army not on active duty, served during World War I, formerly on the staffs

of the Garfield Memorial and Doctors hospitals, Washington, D. C. aged 65, died, January 30, in the Mount Alto Hospital, Washington, of arteriosclerosis and nephritis.

James John Cuono, New York, Long Island College Hospital, Brooklyn, 1909, on the staff of the Columbus Hospital, aged 55, died, January 28.

Edward Jackson Davis, St. Louis, Harvard Medical School, Boston, 1899, at one time physician to the Zuni Indian Reservation at Zuni, N. M., served as treasurer and member of the staff of the People's Hospital, where he died, January 18, of cerebral hemorrhage, aged 72.

Archibald Sayre Dennison * Lynn, Mass., Bellevue Hospital Medical College, New York, 1896, also a pharmacist, fellow of the American College of Physicians, honorary member of the Lynn Hospital, aged 73, died, January 22, of acute coronary occlusion.

Lambros G. Diamessis, Chicago, National University of Athens School of Medicine Greece, 1904, aged 63, died, January 14.

William R. Doyle, Schenectady, S. C., Atlanta (Ga.) Medical College, 1895, member of the South Carolina Medical Association, aged 72, died, January 28, of bronchiectasis.

Leonard Eskey, Wheeling, W. Va., University of the City of New York Medical Department, New York, 1882, member of the West Virginia State Medical Association, for many years company doctor for the Wheeling Friction Company and medical examiner and company physician for the Baltimore and Ohio Railroad, one of the organizers, a director and vice president of the Center Wheeling Savings Bank, aged 92, died, January 17.

Fritz Faltitscher, New York, Medizinische Fakultät der Universität Wien Austria, 1924, assistant physician on the staff of the Mount Sinai Hospital, aged 48, died, January 20, of subacute bacterial endocarditis.

Morris Ritner Faulkner, Vineland, N. J., Hahnemann Medical College and Hospital of Philadelphia, 1895, served during World War I, was chief surgeon aboard the liner *Leviathan*, formerly medical inspector of local schools, a U. S. Pension Examining Surgeon, served as a member of the staff of the Newcomb Hospital, Vineland, and the Atlantic Shores Hospital, Somers Point, aged 70, died, January 24, of cerebral hemorrhage.

John Louis Fomorin, Marathon, Ohio, Medical College of Ohio, Cincinnati, 1888, aged 87, died, January 28.

Charles Freeman, Steubenville Ohio, University of Georgia Medical Department Augusta, 1899, aged 68, died, January 26, of coronary occlusion and diabetes mellitus.

Lawrence Eugene Friedman, St. Louis, St. Louis University School of Medicine, 1930, aged 38, died, January 27, in the Jewish Hospital of cerebral hemorrhage.

Ernest A. Gates, Springfield, Mass., Dartmouth Medical School, Hanover, N. H., 1895, member of the Massachusetts Medical Society, aged 71, died, January 4.

Allen C. Gillespie, Dallas, Texas, Medical College of Alabama, Mobile 1890, at one time staff surgeon at the Agricultural and Mechanical College of Texas, College Station, aged 79, died, January 9.

Alexander James Gillis, Baltimore, College of Physicians and Surgeons, Baltimore, 1914, clinical professor of genito-urinary surgery at the University of Maryland School of Medicine and College of Physicians and Surgeons, received the British Military Cross and the Purple Heart Medal for services during World War I, fellow of the American College of Surgeons, served on the staffs of the Mercy and University of Maryland hospitals, aged 54, died, February 6, of coronary thrombosis.

John B. Gordon, Shawano Wis., Rush Medical College Chicago, 1903, formerly an Alderman and president of the city council, aged 70, died, January 26, in a hotel in Chicago.

W. O. Green * Louisville Ky., University of Louisville Medical Department, 1889, aged 76, died, January 23, of osteitis deformans.

Samuel Eugene Grout, Docena Ala., University of Minnesota College of Medicine and Surgery, Minneapolis 1899, member of the Medical Association of the State of Alabama for many years associated with the Tennessee Coal and Iron Company, aged 69, died, February 4, of chronic cardiorenal disease.

John Mathew Hammons, Louisville, Ky., Meharry Medical College, Nashville, Tenn., 1917, aged 51, died, January 26, of chronic nephritis.

Thomas Henry Hanbidge, Darby, Mont., Bellevue Hospital Medical College, New York, 1890, member of the Medical Association of Montana, aged 88, died December 1, of right hemiplegia

H K Harker, Dayton, Ohio, Pulte Medical College, Cincinnati, 1878, aged 89, died, January 16, of cardiac failure

Charles G Harmonson, Smyrna, Del., Jefferson Medical College of Philadelphia, 1884, member of the Medical Society of Delaware, past president of the Kent County Medical Society, vice president of the Clayton Bank and Trust Company, at one time president of the board of health of Clayton on the staff of the Kent General Hospital, Dover, aged 81, died, February 5, of coronary thrombosis

Raymond Victor Harris, Savannah, Ga., University of Maryland School of Medicine Baltimore 1907, member of the Medical Association of Georgia, aged 62, died, January 23 of angina pectoris

Urban Bunyon Harris, Evanston, Ill., University of Illinois College of Medicine, Chicago, 1914, served during World War I, member of the surgical staff and obstetric consultant at the Martha Washington Hospital, Chicago, aged 51, died, January 24, in Chicago of cerebral hemorrhage

Frank A Hartley, Springfield, Ohio, Starling Medical College, Columbus 1898, member of the Ohio State Medical Association and the American Academy of Ophthalmology and Otolaryngology recently appointed to the post of assistant chief of the emergency medical unit of the Civilian Defense Corps, aged 72, member emeritus on the staff of the Springfield City Hospital, where he died January 18 of coronary thrombosis

Walter Hannibal Henning, New York, Long Island College Hospital Brooklyn, 1903, aged 63, hanged himself January 30

John Joseph Hickey & Peabody, Mass., Harvard Medical School, Boston 1903, for many years on the staff of the Josiah B Thomas Hospital Peabody, and the North Shore Babies Hospital Salem, aged 75, died, January 17, in the Salem (Mass.) Hospital

James E Holden, Collins, N Y, University of Buffalo School of Medicine 1896, member of the Medical Society of the State of New York, served during World War I health officer of Collins, aged 79, died, January 23 in Buffalo of coronary thrombosis

Duke Hunter Huffaker, El Paso Texas, Kansas City (Mo.) Medical College, 1894, member of the State Medical Association of Texas, served as first police surgeon assistant city physician and state quarantine officer, member of the federal pension board for eighteen years, served throughout World War I as a member of the Selective Service Board, aged 75, died, December 29 of heart disease and hypertension

Joseph R Hughart, Morgantown, W Va, Maryland Medical College, Baltimore, 1904, formerly county health officer of Monongalia County, aged 71, died December 2, of aleukemic leukemia

Amy Rawson Humphrey, Glen Alpine N C, American Medical Missionary College, Chicago 1903, for many years on the staff of the Battle Creek (Mich.) Sanitarium, aged 66, died, January 23, of carcinoma of the right breast

James Herbert Irish, Syracuse N Y, New York Homeopathic Medical College and Hospital New York 1899, member of the Medical Society of the State of New York, fellow of the American College of Surgeons, served as a captain in the Syracuse Medical Unit during World War I, on the staff of the General Hospital, aged 72, died January 26, of arterio-sclerotic heart disease

Felix S Jenkins, Pikesville Md., University of Maryland School of Medicine Baltimore, 1887, aged 80, died, January 24, of arteriosclerosis and coronary occlusion

Wylie Little Kell, Columbia Falls Mont., St. Louis College of Physicians and Surgeons, 1909, member of the Medical Association of Montana, at one time member of the board of health of Bridgeport, Ill., attending surgeon for the Montana Soldiers' Home, formerly associated with the Indian Service

on the courtesy staff of the Kalispell (Mont.) General Hospital, where he died, January 10 of cirrhosis of the liver, aged 57

George Alexander Knox, Santa Cruz Calif., University of Southern California School of Medicine Los Angeles, 1906, veteran of the Spanish-American War, aged 78, died, January 28 of coronary disease

Edward Charles Kottcamp, Philadelphia, Jefferson Medical College of Philadelphia 1901, also a pharmacist on the courtesy staff of the Hospital of the Protestant Episcopal Church, formerly on the staff of the Kensington Hospital for Women, aged 69, died January 24 in the Jefferson Hospital of retroperitoneal carcinoma

Florence Marion Loughton, New York, Woman's Medical College of the New York Infirmary for Women and Children New York, 1898, member of the Medical Society of the State of New York, formerly chief medical clinician on the staff of the New York Infirmary for Women and Children, at one time medical examiner for the New York Life Insurance Company and the New York Civil Service Commission, aged 72, died January 15

Charles Le Baron Jr & Major, U S Army, retired Gulfport Miss., University of Alabama School of Medicine 1914, graduated from the Army Medical School in 1917 and in the same year was commissioned a first lieutenant in the medical corps of the U S Army, became a captain and major the following year, retired for disability in line of duty in 1936, served during World War I, aged 50, died January 6 in the Veterans Administration Facility Biloxi of toxic myocarditis and pericarditis

John Lennon, New York, Bellevue Hospital Medical College New York, 1894, member of the Medical Society of the State of New York, aged 75, died January 14

Carl Olander Lind & Seattle, Wash., Medical College Chicago, 1901, had been a medical missionary and teacher in Alaska under the Swedish Mission Covenant Church, served during World War I, aged 71, died January 25 in the Virginia Mason Hospital of coronary occlusion

Joseph Lipshutz, Portland Ore, University of Oregon Medical School Portland 1929, member of the Oregon State Medical Society, clinical instructor of pediatrics at his alma mater, a member of the U S Naval Reserve since 1934, called to active duty on May 1 1941, later became a lieutenant commander, had been in charge of the department of pediatrics at the Naval Dispensary at Long Beach, Calif., and later was attached to the Marine

Corps, aged 37, died December 17 in the South Pacific area as the result of gunshot wounds

Edward Chung Louie, Portland Ore, University of Oregon Medical School, Portland 1939, aged 29, died, December 25, of injuries received in an automobile accident

Ray Lyons, Lanesboro Pa., University of Pennsylvania Department of Medicine Philadelphia 1886, for many years served as county coroner, aged 79, died January 21 in the Barnes Hospital, Susquehanna of coronary thrombosis

John McColl & Wheeling W Va, Hering Medical College, Chicago 1898, aged 80, died, January 19, of arterio-sclerosis and coronary thrombosis

Harvey W McKane, Columbus Ind., Indiana Medical College School of Medicine of Purdue University Indianapolis 1906, for many years director of the division of tuberculosis and communicable diseases, state board of health, formerly associated with the U S Public Health Service, aged 74, died, January 11

Oscar Eugene McWilliams, Anderson Ind., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1899, member of the Indiana State Medical Association, during World War I served as captain in the medical corps of the U S Army, formerly city health officer, president of the board of managers of the Ella B Kehrler Hospital, aged 74, died January 31 of pneumonia

KILLED IN ACTION

LIEUT. COMDR. JOSEPH LIPSHUTZ
M C, U S N R, 1905-1942

Victor Kinnaman Martin * Buffalo, University of Buffalo School of Medicine 1921, on the staffs of the Millard Fillmore and Lafayette General hospitals, assistant surgeon in the eye department of the Charity Eye, Ear and Throat Hospital, aged 48, died suddenly February 2, of coronary thrombosis

Charles Francis Metzger, Bellevue, Pa., University of Pittsburgh School of Medicine, 1918, member of the Medical Society of the State of Pennsylvania, diplomate of the National Board of Medical Examiners, served in the U S Navy from 1909 to 1912, recently an examining physician of draft board number 14 on the staff of the Suburban General Hospital, aged 51, died February 3 in an automobile accident at Avalon

George W. Mitchell, Aldan, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1902, aged 74, died January 25, of diabetes mellitus

Samuel Shaw Moody * Shelbyville, Tenn. Vanderbilt University School of Medicine Nashville 1909, served overseas as a captain in the medical corps of the U S Army during World War I, at one time health officer of Washington County, past president of the Rotary Club of Shelbyville, aged 58, died, January 19, in the Vanderbilt Hospital, Nashville

Sydney Clayton Moore, Benton, Ill., Loyola University School of Medicine Chicago, 1921, member of the Illinois State Medical Society, served during World War I, aged 53, on the staff of the Moore Hospital where he died, January 30, of pneumonia

Matthias Brickell Murfree * Murfreesboro, Tenn. Vanderbilt University School of Medicine, Nashville, 1908, during World War I served overseas as a captain in the medical corps of the U S Army attached to the 104th Infantry 26th Division on the staff of the Rutherford Hospital, aged 61, was killed in an automobile accident near Woodbury, January 27

Henry Martin Norris, East Orange, N. J., Columbia University College of Physicians and Surgeons, New York 1923, member of the Medical Society of New Jersey, member of the senior staff of the Orange (N. J.) Memorial Hospital, aged 44, died January 29, of pernicious anemia

William Walton Odom, Lyons, Ga., University of Georgia Medical Department, Augusta, 1904, member of the Medical Association of Georgia, aged 70, died in January

Mary Goddard Potter, New York, New York Medical College and Hospital for Women, New York, 1903, died January 13

Andrew Henry Panettiere, St. Joseph, Mo., Creighton University School of Medicine, Omaha 1935, member of the Missouri State Medical Association, the American Psychiatric Association and the Missouri-Kansas Neuropsychiatric Association, served as resident in psychiatry at the State Hospital number 2, captain medical corps Army of the United States, began extended active duty in December, 1940, as a tribute to his courageous service the Army named their hospital at Noumea, New Caledonia, the Panettiere Hospital, aged 33, was killed in action in the Solomon Islands, November 23

Albert Herman Riethmuller * Millvale, Pa., Western Pennsylvania Medical College, Pittsburgh, 1907, school physician in Millvale for many years, served on the staff of St. John's General Hospital, Pittsburgh, aged 60, died January 28, of septicemia

Harry Summers Shafer, Denver, Denver College of Medicine 1901, during World War I served as a first lieutenant in the medical corps of the U S Army, served on the staffs of St. Luke's and Denver General hospitals, aged 73, died, January 22, in the Mercy Hospital of paralysis agitans

Clarke Wallace Stewart, Olean, N. Y., Niagara University Medical Department, Buffalo 1898, aged 70, died, January 29, of coronary thrombosis

William Joseph Sullivan, Dunkirk, N. Y., University of Buffalo School of Medicine, 1905, member of the Medical Society of the State of New York, past president of the Chautauqua County Medical Society, for one term a member of the police and fire board, served as director of the Merchants National Bank and of the Chamber of Commerce

formerly on the staff of the Brooks Memorial Hospital, aged 61, died, January 14, of cerebral hemorrhage

Ole Samuel Swennes, Waukon, Minn. Rush Medical College, Chicago, 1894, aged 75, died suddenly, December 20, of coronary thrombosis

Alfred H. Taylor, Salt Lake City, University of Pennsylvania Department of Medicine Philadelphia, 1895, member of the Utah State Medical Association, formerly a federal narcotic agent, aged 77, died, January 30, of complications following a fall

John Taylor, Asbury Park, N. J., Bellevue Hospital Medical College, New York 1893, at one time on the staff of the Asbury Park Hospital, Lying-in Hospital, New York, the Dr. E. C. Hazard Hospital, Long Branch, and the Paul Kimball Hospital, Lakewood, aged 71, died, February 11, of heart disease

Joseph Benjamin Thompson, Bogalusa, La., University of the South Medical Department, Sewanee, Tenn., 1905, member of the Louisiana State Medical Society, aged 68, died January 6, in the Elizabeth Sullivan Memorial Hospital of carcinoma

Walter Randolph Titzel, Chicago, Chicago Homeopathic Medical College 1888, member of the Illinois State Medical Society, aged 77, on the staff of the South Chicago Community Hospital, where he died January 27, of coronary thrombosis

Robert Bruce Tule, Milton, Pa., Jefferson Medical College of Philadelphia 1891, member of the Medical Society of the State of Pennsylvania, aged 76, died January 16, of chronic myocarditis

George R. Turner, Upton, Ky., University of Louisville Medical Department 1888, formerly a pharmacist, aged 78, died January 21, in the Kentucky Baptist Hospital, Louisville, of carcinoma of the stomach

Herbert Hector Utley, Benson, N. C., Baltimore Medical College, 1906, member of the Medical Society of the State of North Carolina, past president of the Johnston County Medical Society, at one time county health officer for many years, had served as physician for the Atlantic Coast Line Railroad, aged 66, died January 15, of coronary occlusion

Harry James Vaughan, Dallas, Texas, Emory University School of Medicine Atlanta, Ga., 1916, aged 50, died January 22, of pneumonia and heart disease

Thomas H. Wagner * Joliet, Ill., Northwestern University Medical School Chicago, 1898, fellow of the American

College of Surgeons, for many years surgeon for the American Steel and Wire Company and for the Chicago, Rock Island and Pacific Railroad, aged 67, chief of the surgical staff of St. Joseph's Hospital, where he died January 18, of uremia and tumor of the bladder

Henry Charles Young, Hiram, N. Y., Albany Medical College 1887, member of the Medical Society of the State of New York, for fifty-five years health officer of Hiram, school physician, aged 81, died January 8, of carcinoma of the lung and of the tongue

KILLED IN ACTION

CAPT. ANDREW HENRY PANETTIERE,
M. C. A. U. S., 1909-1942

DIED WHILE IN MILITARY SERVICE

Bernard Weiss, Brooklyn, University and Bellevue Hospital Medical College, New York, 1936, member of the Medical Society of the State of New York, served as resident on the staff of the Hudson River State Hospital, Poughkeepsie, N. Y., first lieutenant medical corps, Army of the United States, stationed at Fort Niagara, N. Y., where he died, December 29, of acute endocarditis, aged 30

Francis Harold Malee, Butte, Mont., University of Louisville (Ky.) School of Medicine 1935, member of the Medical Association of Montana, served on the staff of the Murray Hospital, called to active duty as a first lieutenant in the medical corps, Army of the United States, assigned to Camp Shelby, Miss., aged 33, died recently in Los Angeles

Correspondence

"COOLING IN SHOCK"

To the Editor—Congratulations on your excellent editorial entitled "Cooling in Shock" in the February 6 issue. Not only have I found the deliberate maintenance of temperatures around 90 F, rectal, in cases of severe trauma most beneficial from the standpoint of shock but apparently consciousness can be returned on a lower level of oxygen compensation, whereas in hyperthermic states there is not sufficient to maintain cerebral function.

After all these years "refrigeration" appears to be coming into a wider appreciation, and some day I hope to see recognition as to what "refrigeration" will do for burns. It controls pain, prevents infection, diminishes shock and decreases loss of serum. In addition the scar formed is pliable and soft rather than hard and firm.

I would appreciate your sending me the references for the statement "the safe range of body temperature deviates far more below than above normal, temperatures down to 90 F can be tolerated for many hours and may actually be life saving when circulation is feeble." I observed this factor during early observations on human "refrigeration."

Would you let me know if some one else has also confirmed this observation?

TEMPLE FAY, M D, Philadelphia

[NOTE—The letter was referred to Major Roswell K. Brown, who replies.]

To the Editor—The wide range of safe deviation of body temperature below normal was demonstrated by Temple Fay several years ago and has been demonstrated since by many others in the treatment of carcinomatosis. I am not familiar with any previous knowledge of general human refrigeration.

"Deliberate maintenance of temperatures around 90 F, rectal, in cases of severe trauma" and "what refrigeration will do for burns" should be matters of great interest. There is ample experimental support for the belief that there is an optimum "subnormal" temperature for shock states at which the metabolism is at its lowest level. Deviation from this optimum "subnormal" level, either warming or cooling lessens the chances of recovery (Elman, Robert, Cox, W. M., Jr., Lischer, Carl, and Mueller, A. J. Mortality in Severe Experimental Burns as Affected by Environmental Temperature, *Proc Soc Exper Biol & Med* 51:350 [Dec.] 1942).

Carefully controlled assistance of the body's cooling mechanism may be quite useful in the future. The important thing right now is to stop the pernicious teaching of external heat for shock. Laymen, first aid workers, nurses and doctors are still being taught to fight against the body's natural attempt to save itself by peripheral cooling. First aid manuals should be radically revised on this point at once.

STATISTICS ON THE PATIENT LOAD OF PHYSICIANS IN PRIVATE PRACTICE

To the Editor—With reference to the special article on "Statistics on the Patient Load of Physicians in Private Practice" by Ciocco and Altman, appearing in the February 13 issue of THE JOURNAL, a few comments are included which it is hoped may add to the value of this most interesting study. Assuming that it is possible to base an ideal physician distribution on the results of mathematical analysis I shall limit my comments to technical analysis of the statistics presented.

At the outset it must be emphasized that the entire scope of the study reported in this article is a cross section analysis of conditions as they reportedly existed at a given period. It would have added considerably to the value of the study if a

time series analysis could have been made as the element of trend, seasonal and cyclic deviations cannot even be reasonably estimated without such studies.

By an analysis extending over a period of time it would be theoretically possible to obtain a trend of the values for patient load by age group, hours of office work per week and so on. Of course, one should attempt to analyze in more detail the sources from which patients are being drawn, with the view of determining whether or not they would be subject to modification if local industrial conditions would change. This in turn would suggest population studies and forecasts for each area studied.

In view of the rather large coefficients of variation which one notes when the standard deviations are divided by the averages in this report, even the application of conclusions based on a time series analysis would seem rather tentative.

The authors have made a commendable and searching analysis of a subject destined to be of increasing interest as time goes on. It is hoped that officials and interested individuals will appreciate the extent of additional statistical analysis required before even tentative assertions could be made and the discrepancy which doubtless exists between actual demand for medical services and the theoretical supply demand situation calculated from statistical analyses which too often are fragmentary, distorted or biased.

RABBITS FOR FOOD OR PREGNANCY TESTING

To the Editor—With American medicine girded for the war effort, the unlimited and unrestricted use of so valuable an edible animal as the rabbit for pregnancy tests seems to be exceedingly wasteful. Even if attempts are made to operate on the rabbits in an effort to reuse them, a large percentage die from the operation, a greater proportion die from infections and the remainder are usually disposed of after a few subsequent tests.

Conservative estimates reveal that in the past year alone upward of 1,000,000 pounds of rabbit meat could have been spared for general food consumption if the animals had not been used for pregnancy testing.

This is of even greater significance when one realizes that probably only a small percentage of the tests are real emergency tests. Moreover, for those instances in which a biologic test for pregnancy is indicated there are excellent time-proved substitutes such as the mouse test (forty-eight to ninety-six hours), employing immature mice, and the "frog" test (six to twelve hours), using the South African xenopus. Both of these animals can be made available in large numbers to the medical profession by efforts in that direction. We have had little trouble in obtaining sufficient African frogs for our own work in pregnancy and there should be no reason why sufficient numbers could not be imported or bred in adequate quantities for general use.

It certainly appears obvious that during this great national emergency there should be a more judicious use of rabbits in pregnancy testing or, even better, one of the other accepted tests employing nonedible animals ought to be used for this purpose, at least for the duration of the war.

MEDICOLEGAL ABSTRACTS

Governmental Hospitals Liability of City for Negligence of Municipal Hospital Intern—The plaintiff submitted to a colostomy in a hospital maintained and operated by the City of Miami, Florida. About two years later the incision became irritated, and possibly infected, and she reentered the hospital for treatment. An intern, assisted by attending nurses, prepared the patient for electrical cauterization of the incision. The intern sterilized the area to be cauterized with surgical alcohol 75 per cent to 90 per cent pure. After saturating a gauze sponge with the alcohol and placing it on the abdomen in close proximity to the place to be cauterized, he had the cautery connected in the electric power socket and attempted to place the hot point on the wound, but when the point approached the patient's body and the pad saturated with alcohol the pad burst into flame. The burning alcohol ran over the patient's body and she was severely burned, back and front, from her neck to her thighs. Subsequently when the city of Miami rejected her claim for damages she brought suit against the city. The trial court overruled a demurrer which the city interposed to the declaration on the ground that the city in operating the hospital was acting in a governmental capacity in the performance of its duty in caring for the public health and hence was not liable for the negligence of its servants. The city then filed pleas to the declaration setting up the defense that it had performed its sole duty when it exercised due care and diligence in the selection of its interns to serve in the hospital. In effect, these pleas were overruled. From a judgment for the patient the city appealed to the Supreme Court of Florida.

The first question for the determination of the Supreme Court was whether or not a municipality in operating a hospital acts in its governmental or its municipal corporate capacity. If it acts in its governmental capacity, there would be no liability for the defendant city. The court held, however, that in operating a hospital a municipality is acting in its municipal corporate capacity, and not in its governmental capacity, and that the liability of the city for damages occurring by reason of the negligence of its employees in operating the hospital is the same as though the hospital were a charity hospital. A previous decision by the Supreme Court of Florida (*Nicholson v. Good Samaritan Hospital*, 145 Fla. 360, 199 So. 344) refused to exempt charitable hospitals from liability for the negligence of their servants. There can be no question, continued the court, that a hospital is as much liable under the doctrine of respondeat superior for the negligence of an intern, who is in nowise an independent contractor but a mere employee, as it is for that of a nurse under like employment. That a hospital is answerable in damages for the negligence of a nurse is well settled. (See *Pensacola Sanitarium v. Wilkins*, 68 Fla. 447, 67 So. 124, *Parrish v. Clark*, 107 Fla. 598, 145 So. 848).

The defendant city relied on the opinion of the Supreme Court of Florida in *South Florida R. Co. v. Price*, 32 Fla. 46, 13 So. 638, and *Atlantic Coast Line R. Co. v. Whitney*, 62 Fla. 124, 56 So. 937. In those cases, said the court, the plaintiffs attempted unsuccessfully to impose liability on railway companies for the negligence of physicians whom the companies had employed to give medical and surgical care and attention to their employees and to persons injured in the operation of their railroads. The rationale of those decisions is that the physicians were in nowise under the supervision and control of the employer but stood in the status of independent contractors, and the duty of the employer railroad company was to exercise only due care in selecting such employees. The court did not believe that those cases were applicable here and indicated that in the light of modern decisions it might even

reverse the views it expressed in those decisions with respect to the physicians who were alleged to be independent contractors.

Aside from all of this, said the court, the negligence complained of in this case was such that it could not be said that the intern was exercising his professional skill and judgment in applying the healing art when he did the thing complained of and which caused the injury. It did not require any knowledge or skill of medicine or surgery for any one of ordinary intelligence to know that if one saturates a gauze sponge with a large quantity of high grade alcohol and then brings a red hot iron into close proximity thereto the saturated materials will immediately ignite and burn. When the intern so carelessly and negligently saturated the materials with alcohol and placed them on the naked abdomen of the patient and then brought a red hot cautery into close proximity therewith he was bound to know what the result would be just the same as one who would drop a lighted match into a gasoline tank might expect an explosion to follow.

The judgment in favor of the patient was affirmed.—*City of Miami v. Oates*, 10 So. (2d) 721 (Fla., 1942).

- West Virginia Medical Association Charleston May 17-18 Mr. Charles Lively 1031 Quarrier St. Charleston Executive Secretary

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Tropical Medicine, Baltimore

22 581-662 (Nov) 1942

- Preliminary Note on Complement Fixation Test for Amebiasis with Antigens Prepared from *Endameba Histolytica* Grown with a Single Species of Bacteria. C. W. Rees, J. Bozicevich, Lucy V. Reardon and Frances Jones. Bethesda, Md.—p. 581.

- Acanthosis Nigricans. A. G. Franks.—p. 97.

Sarcoidosis—To the three chief morphologic variants of dermatologic sarcoidosis,iliary lupoid, Besnier-Boeck sarcoid and the subcutaneous sarcoid of Darier Roussy must be added a fourth the more recently described sarcoid type of tuberculosis of the American Negro. Thomas discusses the 15 cases that she has seen in seven years. 3 patients were white and 12 were Negroes. Two were men and 13 were women. The lesions occurred between the ages of 15 and 49, in half, the initial attack occurred before 30. The course of the disease is benign. Three patients died. 1 of pulmonary tuberculosis which developed within a year of the sarcoid lesions but after all the cutaneous lesions disappeared. 1 died two years after all the cutaneous lesions disappeared and 1 died within nine days of hospitalization of pulmonary infarction due to pressure from tremendously enlarged mediastinal lymph nodes. Five patients, 2 white and 3 Negroes, had a spontaneous recovery, the cutaneous changes disappeared, the enlargement of the lymph nodes diminished and the general health improved. The condition of the remaining 7 patients was relatively unchanged, there were slight exacerbations and remissions. Several organs, skin,

lymph nodes, lungs, spleen and liver, were most frequently involved. Tuberculin tests showed only 7 patients to be anergic. 7 reacted to 1 mg or less of tuberculin. Anticubins could not be demonstrated in the serums of 4 of the anergic patients so examined. The serum protein of 3 patients was determined. There was a decided increase in the globulin fraction. The differential blood count revealed a monocytosis with a count of from 8 to 18 per cent, in more than half of the patients during the active phases of the disease. A variety of therapeutic agents was unproductive of noteworthy results.

Supernormal Circulation in Resting Subjects—In estimating the cardiac output of 1,400 patients, Starr and Jonas encountered 100 in whom the resting circulation was above normal. This condition they call hyperkinesia. The 100 patients were usually underweight and tended to have resting pulse rates above normal. Hyperkinesia was encountered in almost all patients with thyrotoxicosis without cardiac involvement, in most patients with patent ductus arteriosus, often in patients with emaciation and less frequently in those with pulmonary abnormalities, fever, anemia, hypertension and peripheral arteriovenous communications. For the hyperkinesia of 17 patients, no complicating condition could be discovered. These patients with essential hyperkinesia resembled patients with thyrotoxicosis in appearance, but their basal metabolic rate was always normal. In uncomplicated hyperthyroidism and hypothyroidism, the relation between abnormalities of the circulation and the basal metabolic rate is almost 1 to 1. In the average, an abnormal increment or decrement in the basal metabolic rate is accompanied by an equal percentage change in the circulation. In heart disease these two functions are related, but the relationship is more nearly 1 to 0.5. Under such conditions the circulation is less than normal for any given metabolic rate, and the higher the metabolic rate the greater is the circulatory deficit. Deviation from the normal 1 to 1 relationship has been observed in emaciation and in some instances of hyperthyroidism after partial thyroidectomy.

Induced Thiamine Deficiency—Williams and his colleagues restricted the intake of thiamine in the diet of 2 human volunteers to 0.2 mg a day (0.1 mg for each thousand calories) for one hundred and twenty days. They administered a test dose of 1 mg subcutaneously approximately every two weeks during the time of thiamine deprivation. The test dose served as a "periodic partial cure" of the thiamine deficiency; appetite would improve and activity would increase for seven to ten days after each injection. Symptoms and signs of thiamine deficiency were manifested as early as the thirtieth day of restriction. The first objective evidence of abnormality consisted in a decrease in the urinary excretion of thiamine. At the fiftieth day the urinary excretion after a test dose was reduced. After this time, whenever dextrose was given the values for pyruvic and lactic acid in the blood were abnormally high. About this time anorexia and weakness became more severe than they had been and the subjects complained of pares-

thesia of the legs. Later there was objective evidence of dysfunction of nervous pathways and after one hundred and ten days of restriction polyneuropathy (defects of the sensory nervous pathways, loss of tendon reflexes and paralysis of muscles of the legs) was clearly apparent. It responded to large doses of thiamine, but only after many weeks of continuous treatment.

Sulfadiazine in Simple Mastoidectomy Wounds—Tucker and Flake determined the value of sulfadiazine in the management of a controlled series of mastoidectomy wounds. In 16 group A patients the wound of a complete simple mastoidectomy was closed without drainage with sulfadiazine poured in; that of 15 group B patients was sutured without drainage but the patients received sulfadiazine orally and that of 15 group C patients was only drained. The hospitalization period for group A and B patients averaged around ten days, the wounds healed primarily and the tympanic membrane was healed and dry at this time. The wound of only 1 group B patient broke down. The group C patients had the usual prolonged convalescence and their average hospital stay was twenty-one days as compared to ten and nine days respectively for group A and B patients. At this time any one method for the control of wounds in mastoidectomy cannot be advocated, although sulfonamide therapy seems to be of definite value. Certainly the prime requisite for good results is the performance of a standardized thorough, simple mastoidectomy.

Latent Tuberculosis of Tonsils—The 60 patients whose tonsils were examined by Cote varied in age between 4 and 27 years, the majority were less than 10 and only 6 were more than 20. Tuberculous lesions were found in 8 cases that is in 13.3 per cent. The tuberculous lesion was bilateral in all except 1 of the 8 cases. The presence of giant cells was common, necrosis was rare even absent. The surface epithelium was invariably intact, the tubercle bacillus was often present. Of the 8 patients with tuberculosis of the tonsils 2 were more than 20 years old. The previous diagnosis had been active ulcerocaseous pulmonary tuberculosis in 1 of these 2, fibrous noncavitary tuberculosis in the other. Expectoration as well as gastric lavage gave positive results in both. The six other tuberculous tonsils were in children between 7 and 12 years of age. The clinical diagnosis in 5 of these was mild tuberculosis of the lymph nodes and of the pulmonary tissue, in 4 the tubercle bacillus was obtained from the gastric juice. The sixth had been hospitalized for purulent streptococcal tuberculosis. Cervical adenopathy was observed in 6 of the 8 patients with tuberculous tonsils. The author discusses the pathogenesis, symptomatology, complication and frequency of tonsillar tuberculosis. He concludes that in adults tonsillar tuberculosis is of slight importance, because, on the whole it is only a secondary localization in an advanced pulmonary tuberculosis. In children, however, it must be carefully investigated, because it prevents either a secondary localization to pulmonary tuberculosis or a form of primary pharyngeal infection. Tonsillar tuberculosis being latent is detected only by histopathologic examination. This shows that microscopic examination of removed tonsils should be routine. This examination becomes of great importance when a cervical adenopathy exists, tuberculosis of the cervical lymph nodes and tonsillar tuberculosis being frequently associated. Every patient whose tonsils disclose tuberculosis should be subjected to a careful examination, including roentgenography. Tonsillectomy involves no risk in the presence of tonsillar tuberculosis. On the contrary the removal of such tonsils in children reduces the absorption from a tuberculous focus and may prevent the development of tuberculosis elsewhere. The removal of tuberculous tonsils from patients with other tuberculous lesions is rarely followed by aggravation.

Significance of Urinary Calcium, Magnesium and Phosphorus—McCance and Widdowson point out that the urinary excretion of calcium, magnesium and phosphorus by normal persons rises and falls with the intestinal absorption. However the excretion of each does not rise so high or fall so low as absorption may. From the technical point of view a change in a normal person's urinary excretion should be regarded as an indirect but valuable confirmation of a change in intestinal absorption. As in so many other branches of metabolism the function of the kidney is to regulate the stability of the internal environment.

Cold in Treatment of Damage Due to Cold—Greene points out that in true frostbite most of the affected tissue is doomed and no treatment can save it, but some is only chilled and is in the same condition as is the whole affected tissue in immersion foot and trench foot. The treatment of these conditions should therefore be identical. Ancient tradition and modern experiment suggest that while the patient himself is kept warm the affected tissue should be cooled.

Antisulfanilamide Action of Procaine Hydrochloride—The inhibition of procaine hydrochloride on the action of sulfanilamide de Waal and his associates observed was particularly obvious in mice when the procaine was administered

in repeated large doses early in sulfanilamide therapy (5 of 6 mice died). Repeated small doses of procaine resulted in an occasional fatality among infected mice receiving large doses of sulfanilamide. It is difficult to say what constitutes a harmless dose of procaine since this will depend on the amount of sulfanilamide in the body but by comparison with the results obtained in mice, 20 cc of a 3 per cent solution of procaine should prove harmless to a patient whose concentration of sulfanilamide in the blood is 3 mg per hundred cubic centimeters. However as the sulfonamide- p aminobenzoic acid ratio cannot yet be determined this dose might well be cut by half or two thirds. This amount should prove sufficient in minor surgical operations. The occasional large dose of procaine in human beings and in mice appears for the most part to have no lasting inhibitory action. Exceptionally however mice died (2 of 9) after such sporadic doses of procaine. Therefore it seems unwise to use clinically massive doses of procaine. When a massive local anesthetic is required a drug not allied to p -aminobenzoic acid, such as cocaine, metocaine or pontocaine hydrochloride should be used.

Shock and the Sympathetic Nervous System—Tomb reports that he has seen the following effect of ergotamine (1.00 grain [0.001 Gm] intramuscularly) in a case of incipient shock due to crushing of the thumb. The patient was faint, pale and sweating profusely. Ten to fifteen minutes after the ergotamine was given sweating ceased completely and the cutaneous circulation as evidenced by the patient's color was restored to normal, although intentionally no morphine had been given to relieve pain and to block shock impulses. The author thinks that the action of ergotamine would be still more evident in more serious cases as shock apparently is due to sympathetic overstimulation.

*Antagonism Between Procaine and the Sulfonamides J W Legge and E B Durie—p 561

Procaine Hydrochloride and the Sulfonamides—A method for estimating procaine hydrochloride and p aminobenzoic acid in the presence of each other is presented by Legge and Durie. The method shows that procaine is hydrolyzed to p -aminobenzoic acid by an esterase present in human blood. In the mouse injected procaine is hydrolyzed to p aminobenzoic acid, and then some of it is acetylated to p -acetylamino benzoic acid. In mice infected with a streptococcus and being treated with sulfanilamide the injection of procaine caused a slight increase in the mortality rate. With severe infection or with massive damage to tissue procaine or other similar local anesthetic agents are contraindicated if any sulfonamide drug is being used.

Experiences with Compound of Dihydrodesormorphine Scopolamine Hydrochloride in Surgery G Drack—p 900
Direct Tolerance Test Preceding Blood Transfusion R Bucher—p 903

Duration of Renal Tuberculosis—Suter investigated 260 surgical cases of renal tuberculosis to determine (1) the frequency of a secondary localization of tuberculosis before the outbreak of the renal tuberculosis (2) the incidence of intermediate symptoms between such a first dissemination and the onset of renal tuberculosis, (3) whether in cases of renal tuberculosis in which localization in another organ did not precede or at least was not observed there were perhaps other signs that indicated the time of renal infection and (4) the behavior of the cases in which urogenital tuberculosis was the first demonstrable secondary localization. In 73 cases renal tuberculosis was preceded by dissemination. The interval between this dissemination and the renal tuberculosis varied greatly. Intermediate symptoms were generally indicative of urogenital tuberculosis dating back only a year and a half. Although renal tuberculosis can exist a long time without manifesting symptoms it does not seem likely that this silent period will persist for ten years. Presumably the production of the specific renal focus did not take place at the first bacillary dissemination into the peripheral organs but at a later time and without causing definite symptoms. In the 187 cases in which renal tuberculosis was the first localization the time of the manifest existence of symptoms was somewhat longer, nearly two years. In 56 cases with completely destroyed kidneys the period during which symptoms existed varied between one month and fifteen years, but the average of two and one-half years was somewhat longer than in the other cases. When renal tuberculosis was associated with or preceded by tuberculosis of the prostate or epididymis, it could often be observed that the localization in the kidney did not concur with that of the genital organs but that an interval sometimes of several years' duration separated the two. The author reports cases in which first a genital and later renal tuberculosis developed. Determination of the duration of renal tuberculosis is difficult, because the infection of the organ nearly always takes place without symptoms and even the anatomic aspects do not permit a reliable determination.

Bol del Depart de Salub Pub Mexico, D F

5 99-185 (June) 1942 Partial Index

- *Yellow Fever C Ortiz Mariotte—p 123

Yellow Fever—The incubation period of yellow fever, according to Ortiz Mariotte, is three to six days. There are no prodromal symptoms. There is a sudden onset with acute chills, followed by high fever, headache, backache, epigastric distress and vomiting. Swollen gums, leukopenia, irregular pulse, albuminuria, vomiting and jaundice occur between the second and fourth days. The classic type of yellow fever is entirely under control, but there are still two uncontrolled endemic areas of jungle type of the disease, one in Africa and the other in Brazil. Jungle type is the ordinary yellow fever from the etiologic, clinical and immunologic points of view. The author emphasizes the epidemiologic importance of (1) continuation of antimosquito campaigns in sea ports, (2) establishing these campaigns in air ports as well as in landing grounds, (3) establishing a department for examination of suspected passengers from endemic areas and places for quarantine and treatment of patients, (4) vaccination of workers in epidemic areas, and (5) viscerotomy of the liver of persons dying from suspected yellow fever. There is no specific therapy for the disease. The patient is to be kept in bed from the first day of the disease and all during it. Sponging and ice to the head are indicated to lower the fever. Pieces of ice, cocaine 0.015 Gm by mouth and 0.03 Gm hypodermically are administered to combat vomiting. Isotonic solution of sodium chloride by hypodermoclysis and intravenous injections of dextrose solution are indicated. Immune serum therapy does not influence the course of the disease when administered after onset of symptoms.

Morphologic Manifestations of Oxygen Hunger and Its Significance in Mechanism of Allergic Tissue Reactions Y M Lazovskiy—p 15
*Clinical Aspects of Transfusion of Cold Preserved Blood—A P Kiyashev—p 29
*Blood Transfusion in Renal Diseases Z I Chukanova—p 34
*Use of Carbon Dioxide-Oxygen Mixture in Low Barometric Pressure V M Tarasenko—p 39

Transfusion of Cold Conserved Blood—Kiyashev used unheated and refrigerated conserved blood in 155 transfusions. He began with the unheated blood and gradually decreased the temperature to 4°C. The dosage varied according to the indications. For hemostasis and for stimulation of the hemopoietic organs 100 to 200 cc was used, while patients with excessive loss of blood, progressive anemia or traumatic shock received 400 to 450 cc of blood. The rate of transfusion was 6 to 20 cc a minute. With decreasing temperature of the transfused blood the rate was slowed down and with rising temperature the rate was increased. Febrile posttransfusal reactions were observed in 53 cases (34.2 per cent). This does not exceed the percentage of reactions after transfusion of fresh citrated blood and is considerably lower than after transfusion of heated blood. In all cases the symptoms disappeared within five to six days. There were no deaths. The fact that in many cases the conserved blood had to be transported for long distances before being used may have contributed to the large number of posttransfusal reactions. The technique of transfusion and date of preservation of the blood seem to influence the outcome much more than the temperature of the blood. The transfusion of cold conserved blood calls for a simple technique is entirely safe and is biologically effective in all cases in which blood transfusion is indicated.

Blood Transfusion in Renal Disease—Chukanova performed forty-five blood transfusions on 24 patients. Among these 8 had lipid nephrosis, 8 had chronic nephritis with a nephrotic component and 5 had acute glomerulonephritis. Compatible blood was used in amounts varying from 100 to 200 cc. In some cases the transfusion was repeated two or three times at intervals of ten, fifteen and twenty days. In moderately severe cases of lipid nephrosis with preserved renal function, blood transfusion produced temporary improvement sometimes lasting two to three months. The patients with chronic nephritis showed an exacerbation of renal symptoms during the first few days after transfusion. These manifestations disappeared and were followed either by definite improvement or by a return to the original state. The results of transfusion were beneficial in all 5 cases of acute glomerulonephritis. The intensification of renal symptoms observed during the first days disappeared after five or six days. There was a mild febrile reaction during the first twenty-four hours. No pronounced fluctuations in blood pressure resulted from transfusion. The author considers insufficiency of the cardiovascular system, especially hypertension, and severe renal insufficiency as definite contraindications to blood transfusion in patients with renal diseases.

Inhalation of Carbon Dioxide-Oxygen Mixture in Low Pressure Atmosphere—Tarasenko points out that oxygen inhalation alone is not enough to prevent hypoxemia in aviators flying at an altitude exceeding 12,000 meters. Inhalation of a mixture of oxygen and carbon dioxide increases the amount of oxygen liberated by the tissues and thus to some extent compensates for the deficiency of oxygen in the inhaled air. The author carried out forty-six experiments on 16 individuals in the low pressure chamber. The atmospheric pressure was reduced to correspond to an ascent of 10,000 to 13,000 meters above sea level. In the majority of cases the carbon dioxide-oxygen inhalation stabilized the cardiac rhythm, maintained pulmonary ventilation at a higher level and increased the subjective sense of well-being as compared with oxygen inhalation. Thus, inhalation of the mixture containing gradually increasing percentages of carbon dioxide corresponding to a decreasing barometric pressure preserves the carbon dioxide of the organism and facilitates a more complete utilization of oxygen by the tissues. This was demonstrated by the maintained working capacity and the absence of any definite changes in the composition of the urine. Tarasenko attributes his three negative results to an inadequate dosage of carbon dioxide.

Book Notices

Food Control in Great Britain International Labour Office Studies and Reports Series B (Economic Conditions) No 35 Paper Price \$1.25 5s Pp 272 Washington C Montreal International Labour Office London P S King & Staples Ltd 1942

Much has been said about the rationing of foods in Great Britain, and the present volume describes some of the food problems which that country is meeting. There is a chronology of all food control orders issued in Great Britain from Aug 31 1939 to the early part of 1942. It is pointed out that the first requisite of any food administrator is courage and secondly the realization that food control is intended to help maintain the physical status and the morale of consumers. The steps which Great Britain has undertaken to meet the problem are described under the headings of agricultural policies, control of supplies and of channels of distribution, rationing and priority distribution and food price control policies. There is described in precise language but not in great detail the steps that have been undertaken to provide children with milk, with sources of vitamin C and with fish liver oils or other sources of vitamin D. Point rationing which applies only to canned goods is described briefly. Meat is rationed on the basis of the amount of money that can be spent for this item. This method allows for variations in quality and for different amounts of bone and connective tissue in the different cuts of meat. Some groups in the population receive special treatment in the rationing program. These are children invalids, persons suffering from certain diseases such as diabetes or gastrointestinal disorders, vegetarians and certain classes of workers. The book no doubt has received thoughtful study by persons concerned with the establishment of food rationing programs in this country.

The general reader will be most interested in knowing how the system works. Reports of British medical observers indicate that the general health of the civilian population is being maintained and the poor class of people probably have a better nutritional status than they did before the war. There is still need for education and especially for increasing and conserving the supply of vitamin C. Thus E M Widdowson and R A McCance in a report on *The War and Schoolboys' Food* (*Lancet* 2 689 [Dec 2] 1942) have pointed out that the children's diets which they examined contained as much protein, calcium, iron and thiamine in 1942 as did the diets of prewar days, rationing having reduced the amount of meat, fats and sugar in the diet and having increased the amounts of bread, oatmeal, cakes, biscuits and root vegetables, but there was some indication that some of the schools were not taking full advantage of their opportunities or assuming all their responsibilities. Among other things it was emphasized that there should be close cooperation between the garden and the kitchen. During war time, at any rate, they have written, some members of the domestic staff should remain on duty during the summer holidays, to store and preserve the garden produce. At one school the entire crop of tomatoes grown in the school garden had to be given away, as the school was closed down when they ripened and there was no one available to deal with them. Of course this is simply an isolated instance but if lessons are to be learned from the experience of others it is well to know not only the successes but the failures of the procedures adopted by other countries in the rationing of food.

The Biology of the Negro By Julian Herman Lewis PhD MD Associate Professor of Pathology University of Chicago Chicago Cloth Price \$5 Pp 433 Chicago University of Chicago Press 1942

Approximately one tenth of the people of the United States are Negroes. The Negro race in addition makes up a large portion of the population in other parts of the world. Although these are statements of fact it is a difficult problem to determine just what people should be included under the term 'Negro'. This book by Lewis on the biologic characteristics of the Negro fulfills a real need and helps to define the term 'Negro'. It is principally, although not exclusively, a comparison between the biologic characteristics of the American Negro (who is in some respects different from his African counterpart) and the American white person.

Lewis discusses all the real and supposed biologic differences between the Negro and the white person in this country. Some

of the alleged differences he explodes as unfounded in fact and others he establishes as relatively true. The comparative nature of the study is emphasized by the statement that in the United States the people classed as Negroes are a heterogeneous group composed of various degrees of intermixture of African and white blood. Lewis discusses the inheritance of skin color, the commonly claimed differences in size and configuration of the brain in the Negro and in the white person, the deeply held belief of an offensive odor which Negroes and white persons attribute to each other and many other asserted racial differences. Much space is devoted to tuberculosis and syphilis in the Negro. The incidence of these diseases in the Negro is unquestionably high. It is however questionable as to what are the relative roles played by inherited predisposition and economic squalor. Certainly the latter plays a large if not actually a predominating part.

There are a few minor criticisms. On page 78 the author uses the word interdicted when he clearly means denied. On page 154 he says ranging from an imperceptible amount of white blood to apparently full-blooded Africans when he presumably means predominating instead of imperceptible. One chapter is entitled Medical Diseases and another Surgical Diseases. It is not clear why peptic ulcer for example should be included under the surgical diseases.

This book gives a much needed and timely discussion of an important subject. At least for those with biologic training it should serve to clarify opinion on the true similarities and true differences between the Negro and the white man in America.

A Curriculum for Schools of Medical Technology By Isriael Davidsohn MD Director of Laboratories and Pathologist Mount Sinai Hospital Chicago Recommended by the Board of Registry of the American Society of Clinical Pathologists Second edition Paper Price \$1.75 Pp 47 Muncie Ind Registry of Medical Technologists 1942

Emphasis is placed on the presentation of an organized outline of instruction which might be looked on as a teaching plan for schools for clinical laboratory technicians. This edition has been thoroughly revised and enlarged with the assistance of many suggestions from pathologists in various parts of the United States. Considerable information is included in the introduction which is of value to the pathologists directing schools for clinical laboratory technicians and emphasis is placed on the important divisions of the laboratory training. The curriculum is adaptable to training programs ranging from twelve to twenty-four months in duration. Most of the curriculum is composed of teaching guides containing the subjects to be presented each week. Assignments are included under the heading of each subject and a bibliography is arranged so that selected references are given with each assignment. The order of progression of these assignments appears to be logical. The curriculum is recommended for instructors and will also serve as a notebook for individual students.

Ovarian Tumors By Samuel H Geist MD Attending Gynecologist Mount Sinai Hospital New York Cloth Price \$10.50 Pp 527 with 266 illustrations New York & London Paul B Hoeber Inc 1942

This book gives a comprehensive summary of the knowledge of ovarian tumors. The classification and the well illustrated morphologic descriptions of these tumors are based on the current conceptions of their histogenesis. Good use has been made of the large amount of material the author himself has observed and studied and the extensive bibliographies at the ends of the chapters testify to the thoroughness of his literary studies. The clinical manifestations, the diagnosis and the treatment of ovarian tumors receive careful attention. Only general mention is made of radiotherapy. The book is a valuable addition to the literature in its field.

Miracles of Military Medicine By Albert Q Maisel Cloth Price \$2.75 Pp 373 New York Duell Sloan and Pearce 1943

In this book the public is given information in easily understandable form regarding the development of the sulfonamide compounds, new anesthetics and surgical procedures used in the war. Several of the chapters concern the work of the Russians. Much of this report is so incomplete as to make difficult a comprehension of just what the scientific procedures really involve. Altogether however the book serves as a most useful introduction to some of the chief contributions of medical research in the war effort.

POSSIBLE INCIPIENT CATARACT OR EPIDEMIC KERATOCONJUNCTIVITIS

To the Editor—A woman aged 55 has been complaining of blurred vision under sunlight and artificial light and also when snow is on the ground. The previous medical history and all laboratory examinations have been negative. The retinal vessels and the disks are normal. Her vision has been improved by refraction but not the blurring. She was examined by two good ophthalmologists. One diagnosed incipient cataract, the other epidemic corneal conjunctivitis. With this disagreement between specialists my patient and I are in the middle. Can you give me the differential diagnosis between the two conditions and what, if anything, could be done for the blurring that has been the main symptom in her case? Would vitamins help in either case and if so which ones and in what doses?

M D New Jersey

ANSWER—It is possible that both ophthalmologists may be right, in other words, that the patient does have both incipient cataract and epidemic keratoconjunctivitis. The latter condition nearly always is accompanied by some inflammatory symptoms, that is, some redness of the ocular conjunctiva, slight secretion and a roughness of the corneal epithelium which, however, may be rather difficult to detect without special means of examination. Incipient cataract, on the other hand, causes no congestion and can always be seen with the ophthalmoscope after the pupil has been dilated. There should be no difficulty in distinguishing between the two conditions, although modern means of examination are required. In the case of cataract the only treatment available is the proper correction in glasses, which does not do away with the sensation of blurry vision. That only minimizes it. In the case of epidemic keratoconjunctivitis the haziness of the cornea, which is the cause of the blurry vision, usually disappears almost entirely but this sometimes takes a period of weeks or even two or three months. Treatment of this condition is not satisfactory, but it does tend to heal and clear up spontaneously, in fact practically always does so. In some cases slight scarring is left in the corneal epithelium and superficial stroma, which causes the sensation of blurry vision to persist but rarely reduces vision to any serious extent.

BREAST FEEDING OF TWINS AND TRIPLETS

To the Editor—Could you provide me with some information on the proper procedure of breast feeding in the case of multiple birth in which the mother wishes to nurse her babies? Would it be all right for the babies to nurse one after the other at different breasts at regular intervals? Would it be better to skip a breast feeding and give the infants bottles so that the breasts might fill or would it be best to deprive one baby of the breast and let the weaker one nurse? What would happen in the case of triplets would one see to it that each of the infants got an occasional breast feeding or should all the babies be put on a formula? What would be the best feeding schedule for a set of twins? I have consulted several books on pediatrics but have found no reference to such a feeding problem.

M D New York

ANSWER—For twins the best procedure is to allow number 1 to nurse at the left breast, followed by number 2 at the right breast. At the next regular feeding time number 1 nurses at the right breast and number 2 at the left. In this way differences in breast secretion are equalized. Usually fifteen minutes is ample for each nursing time, and a four hour schedule of nursing allows time for the breasts to fill. If a complementary feeding is necessary it may be given after each nursing. If one of the twins is too small to nurse properly, the milk should be expressed by hand or by pump, and the majority given to this one. The larger one can nurse, after the pumping has been done, and this will serve to stimulate the breasts.

In the case of triplets the same procedure is carried out, except that one is given an artificial feeding at each nursing time and the next time is nursed and another infant given the bottle. Occasionally a mother may have enough milk for all three to nurse, in this event the third infant should nurse from both breasts after the other two have nursed at individual breasts.

RASH FROM DIETHYLSTILBESTROL

To the Editor—Can you give me any new information about the side effects of diethylstilbestrol especially cutaneous rashes? A woman had a normal delivery on Nov 22 1942. As she did not have any milk on a previous confinement, she did not want to try to nurse the baby this time. I put her on diethylstilbestrol, 5 mg three times a day for two days to suppress lactation. This she took on Nov 24 and 25, 1942. On November 26 she broke out in a fine rash on the face and upper part of the chest and later this spread over the entire body. Her tonsils had been removed several years before and her throat and tongue did not show any signs of scarlet fever. The hospital put her on infectious precautions, with gowns masks and saponated solution of cresol, which upset her nervously. She had some fever up and down for about three days which sulfadiazine cleared up. As she was nervous and upset I thought that consultation would be advisable. One of the medical chiefs of the hospital looked her over and he felt as I did namely that the rash was an untoward effect of diethylstilbestrol and not scarlet fever. The rash gradually disappeared and her skin cleared up. I spoke to several of the physicians here and none knew much about cutaneous rashes due to diethylstilbestrol. Several said that they had heard about it but none had himself seen a case. Any information you can give me will be appreciated.

G H Miller MD Cranbury N J

ANSWER—The use of diethylstilbestrol has been followed by a number of relatively minor complications and some mention has been made of cutaneous rashes. These are far from frequent and they are not permanent or serious. When such cause for a rash is suspected, no other suggestions seem available than the withdrawal of the synthetic estrogen to watch for the subsidence of the rash.

GROWTH OF HAIR

To the Editor—Will you please advise me of the latest scientific knowledge concerning the effect of cutting on hair growth? I refer especially to head hair. During my medical training dermatologists were certain that by cutting the hair often and close the hair would thereby not be stimulated to grow faster. Beauty parlor experts beauticians and the like tell us that cutting does stimulate hair growth. What as far as is known today is the truth? Does a reasonable amount of water on the head as for shampooing have anything to do with falling hair or dandruff? provided natural oil is replaced frequently by some proper preparation? Some light here will help settle some arguments for me.

T G Harvey MD, Mars Hill Maine

ANSWER—Hair grows according to plan. The destiny of lanugo hair is a short growth, that of scalp hair a much greater length, varying in different races and different individuals. Left undisturbed, hair will grow to its destined length, then stop growing and after a time fall out. Investigation has shown that short hairs, such as those of the eyebrows, after growing at the regular rate for a time, may cease growing for a comparatively long time and then resume growth. Scalp hair, on the contrary, is believed to grow almost continuously for nearly its whole life, attaining its full length in four years or more and remaining only a short time before loosening and falling out (Danforth, C H. Studies on Hair with Especial Reference to Hypertrichosis, *Arch Dermat & Syph* 76 12 [July] 1925). Scalp hair grows about 0.4 mm a day whether cut or not. Trotter's investigation, referred to by Danforth (*ibid* p 195 [Aug] 1925) showed that the rapidity of growth varies with the diameter of the hair.

The reasonable use of water for washing the hair is beneficial, removing dirt and stimulating circulation. Water applied daily to facilitate hair dressing, to make the hair obey the lady's comb, is harmful because it permits the man to neglect brushing, one of the best stimulants for the scalp. The same criticism applies to the application of oil or grease if it allows brushing to be neglected. Most scalps, if well brushed every day, will produce enough oil to keep the hair in place without artificial additions. There is no objection to brillantine or oil if the brushing is faithfully performed.

The wet comb method of hair dressing encourages dandruff for the same reason, because it encourages neglect of the massage obtained when the hair is well brushed. This is one of the best preventives of dandruff and the form of hair loss resulting from seborrheic dermatitis.

DEODORANT FOR SICKROOMS

To the Editor—Will you kindly advise me of a medication to use in the sickroom as a deodorant for smell of cancer cases?

Elwood T Quinn MD Jenkintown Pa

ANSWER—Chlorinated lime, placed in wide, shallow pans or preferably china or earthenware dishes, to a depth not exceeding one half inch, is often used. It acts by oxidation and absorption of moisture and hence is most effective if humidity is relatively high. It is a bleaching agent, destructive of color and many kinds of organic materials. It should be renewed if and when the surface becomes crusted. Many hospitals use electrical units in which a fan draws the air in the room through a deodorant solution.

EFFECT OF SERUM GONADOTROPIN AND CHORIONIC GONADOTROPIN ON THE HUMAN OVARY

ERIK RYDBERG, M D

AND

K PEDERSEN-BJERGAARD PH D

COPENHAGEN, DENMARK

At present, therapeutic experiments are carried out almost exclusively with two kinds of gonadotropic preparations, namely one prepared from the serum of pregnant mares and one derived from the urine of pregnant women.

In animal experiments the active principle prepared from the serum of pregnant mares—which in this paper will be designated as serum gonadotropin—has proved to stimulate the maturing of the ovarian follicles and to produce ovulation and the formation of corpus luteum.

The principle prepared from the urine of pregnant women appears to be formed in the placenta and will be designated as chorionic gonadotropin. In animal experiments its effect has differed with the species examined. From the observations reported so far it appears that chorionic gonadotropin in rodents, through cooperation with the pituitary of the animal, is able to produce a reaction similar to that obtained with serum gonadotropin. It is this effect that forms the basis for the Aschheim-Zondek test for pregnancy. In hypophysectomized animals an entirely different effect has been observed, namely luteinization of the theca without any maturing of follicles or corpus luteum formation. In experiments on monkeys, Engle¹ found that chorionic gonadotropin, in contrast to what might be expected, has an inhibitory effect on the ovarian function, and he even found regressive changes in the ovaries after such treatment.

Experimental studies have been carried out on human beings with both of the aforementioned gonadotropic principles. The substance was given to patients who were to be operated on, and subsequently the ovaries were examined at the operation—or, in some instances, an ovary was removed for microscopic examination.

The action of serum gonadotropin was studied in this way by Westman² who found that the substance stimulates the development of the follicles and leads to a cystic enlargement of them whereas it does not produce rupture of the follicles or formation of corpus luteum.

Also Watson Smith and Kurzrok³ employing injection of the same preparation as that used by Westman found cystic changes in the follicles and luteinization of the theca and exceptionally, of the granulosa too.

Davis and Koff⁴ were able by intravenous injection of serum gonadotropin to produce ovulation and formation of corpus luteum as well as maturing of the follicles. These observations have been confirmed by Siegler and Fein⁵.

Similar experiments have been carried out with chorionic gonadotropin. Hamblen and Ross⁶ found no effect from this treatment on the human ovary. Nor was Westman⁷ able to see any distinct effect from the injection of chorionic gonadotropin alone, in several instances on the other hand in which he first treated the patient with serum gonadotropin and subsequently with chorionic gonadotropin he found changes which he interpreted to indicate that the first substance had produced a ripening of the follicles which later went on to luteinization elicited by the chorionic gonadotropin.

Therapeutic experiments in cases of ovarian dysfunction have given rather divergent results. Positive results have been reported following treatment of amenorrhea both with serum gonadotropin⁸ and with chorionic gonadotropin,⁹ besides in combined treatment with these two substances (Rydborg,⁹ Rydborg and Østergaard,⁹ MacGregor¹⁰ and Westman¹¹).

Other authors have warned strongly against the employment of the gonadotropic substances in the therapy and in June 1940 the Council on Pharmacy and Chemistry of the American Medical Association¹² published a report in which it said in conclusion that the treatment of ovarian disturbances with chorionic gonadotropin for the present has no rational foundation.

In recent years in the University Clinic of Gynecology, Copenhagen we have carried out some experi-

ments with gonadotropic substances along various lines, an account of them has been given in several publications.⁹

The present work will deal with our observations as to the dosage and combination of serum gonadotropin and chorionic gonadotropin preparations, and as to the immediate effect on the functions of the ovary in cases of amenorrhea.

Chart 1—Case of amenorrhea treated with chorionic gonadotropins. In the charts A shows dosage of serum gonadotropin and B of chorionic gonadotropins.

The general indications for treatment and the permanent results obtained will not be dealt with here, but the reader is referred to the paper by Rydberg and Østergaard¹⁰ of 1939 in which our material at that time is described and classified from clinical points of view.

In the first therapeutic experiments performed by one of us (Rydberg) only chorionic gonadotropin was employed. As a rule, 1,500 international units was injected twice a week, and the treatment was continued for several weeks. About one half of the patients treated in this way reacted with bleeding, and on microscopic examination the endometrium was found to be in the secretory phase. From the studies on this material there could be no doubt that chorionic gonadotropin alone in certain cases of amenorrhea was capable of producing true menstruation.

Owing to the experimental experiences gained in the following period, we subsequently adopted a combined method of treatment, commencing with serum gonadotropin and continuing with chorionic gonadotropin. This form of treatment proved more effective, at least as far as the immediate effect is concerned, and hence we have continued with this method. If the doses given were sufficiently large, this combined treatment was capable in a majority of cases of secondary amenorrhea to establish a really complete cycle, in many of these cases the restored ovarian function kept on also after discontinuance of the treatment.

With the experiences gained in this way, various questions arose concerning the mode of action of these preparations and their expedient administration in therapy—questions that suggest themselves but often are difficult to answer since clinical experimentation implies a good many considerations that are absent in experiments on animals, and it thus takes a longer time to gather sufficient experiences for definite conclusions.

Chart 2—Case of amenorrhea treated with serum and chorionic gonadotropins.

It has already been pointed out that the gonadotropins have various actions in different kinds of animals and that the opinions of their action in the human being still are highly divergent. Naturally the fact that a given type of treatment in a number of cases results in the effect desired is not a sufficient basis for conclusions as to the mechanism of the effect of the gonadotropic preparations employed. Real insight into the action of these substances may be gained only through accurate analysis of the cases under treatment and determination of the hormone excretory products that are characteristic of the two phases of the ovarian

cycle, together with examination of the endometrium at the proper periods of time.

Some diagrams are presented of hormone-analytic records and therapeutic measures in a number of cases of amenorrhea in which rather thorough examinations have been made, in connection with the diagrams we shall present our conclusions as to the mode of action of the preparations employed and the dosage required. The cases here reported are selected from a large number of cases of amenorrhea, the total material will be worked up subsequently according to the clinical angle.

THE HORMONAL ANALYSIS AND THE PREPARATIONS EMPLOYED

In the studies here reported, quantitative determination was made of the estrogenic substances in the urine before and during the treatment, besides, in several cases, of pregnandiol under the treatment.

The excretion of estrogens was determined prior to the institution of treatment and throughout the treatment with gonadotropic substance in order to ascertain a possible ovarian stimulation. We have determined

Chart 3—Case of amenorrhea treated with serum and chorionic gonadotropins.

the content of estrogenic substances in the urine after the method given by Kemp and Pedersen-Bjergaard¹³ with this modification that the congo-acid urine before benzene extraction is mixed with an additional 80 cc of concentrated hydrochloric acid per thousand cubic centimeters of urine, so that the ensuing heating causes hydrolysis of possibly combined forms of estrogenic substances. The extracts containing the total estrogenic activity were dissolved in oil and titrated on adult castrated female mice. In normal menstrual cycles the output of estrogens demonstrated after this method is from 15 to 150 mouse units per twenty-four hour output of urine.

In some of our cases we have further determined the output of pregnandiol during the treatment in order to ascertain a possible luteinization of the ovaries. As is well known, pregnandiol is an excretion product of progesterone, isolated first by Venning and Browne¹⁴ as sodium pregnandiol glyconate. The same authors¹⁵ have later shown that pregnandiol is excreted normally during the latter half of the intermenstruum, i.e. in the

corpus luteum phase We have determined the amount of sodium pregnandiol glycuronate in the urine gravimetrically after Venning's¹⁶ method, this substance being shaken out of the urine by means of butyl alcohol recrystallized by means of acetone dried and weighed Pregnandiol itself, which has about the same molecular weight as progesterone, makes up about 60 per cent of the glycuronate The values given for excretion of pregnandiol in charts 9 to 14 are calculated from the values obtained for the glycuronate output In women with normal menstruation the pregnandiol output determined after this method is stated not to exceed 8 mg in twenty-four hours

The values recorded in the charts for estrogens and pregnandiol show the twenty-four hour output, they are averages of the excretions for two to three days as a rule, as is evident from the graphs The analyses were carried out in the biologic laboratory of Løvens kemiske Fabrik under the direction of one of us (Pedersen-Bjergaard) The preparations here employed are (1) serum gonadotropin and (2) chorionic gonadotropin prepared by "Løvens kemiske Fabrik"

Chart 4—Case of amenorrhea treated with serum and chorionic gonadotropins

Both preparations are perfectly free from estrogens Both are standardized by comparison with the international standard preparation, and the potency is given in international units¹⁷

GRAPHIC PRESENTATION OF SOME TREATED CASES OF AMENORRHEA COMMENTS

Explanation of the Signs in Charts 1 to 8—The stepped curve gives the estrogen output in the urine per day in mouse units When this curve is drawn in a dotted line it means that the actual values were not determined and that at any rate they fall below the value indicated by the dotted line The dotted line to the extreme right in chart 7 (in continuation of the unbroken line) indicates that here it was not possible to follow the usual scale of the ordinate because of the very high values in this section The vertical dotted line indicates injection of serum gonadotropin in international units and the vertical solid line injection of chorionic gonadotropin in international units

Charts 1 and 2 illustrate two successive treatments of the same patient—a patient with primary amenorrhea First she was given chorionic gonadotropin alone

and in a subsequent treatment she was first given serum gonadotropin and, after this, chorionic gonadotropin

In this case, as will be noticed the treatment with chorionic gonadotropin alone 24 000 international units, resulted in a decided increase in the output of estrogens, and a bleeding appeared after the discontinuance of

Chart 5—Case of amenorrhea treated with serum and chorionic gonadotropin

the treatment At this time, however, the endometrium was only in the proliferation phase From these results the only conclusion is that the chorionic gonadotropin in this case when given alone had a follicle stimulating effect but no luteinizing

It has already been pointed out that the follicle stimulating effect of this principle is characteristic of the rodents, while it has not been practicable by direct examination to ascertain any follicle stimulating effects on the ovaries of patients receiving this treatment In a few other cases too we have seen chorionic gonadotropin alone able to produce bleeding from the endometrium in the phase of proliferation

Now we have more effective methods for adequate stimulation of the ovary, and we presented chart 1 merely because it illustrates the fact that the chorionic gonadotropin may act exclusively as a follicle stimulating agent

Subsequently the same patient was treated first with serum gonadotropin and later with chorionic gonadotropin (chart 2) Also this treatment resulted in a considerable increase in the output of estrogens and bleeding, but this time the endometrium had undergone the clear premenstrual change at the appearance of the bleeding

Charts 3 and 4 illustrate therapeutic experiments in which the treatment commenced with relatively small

Chart 6—Case of amenorrhea treated with serum and chorionic gonadotropins

doses of serum gonadotropin the dose was then increased slowly, after which chorionic gonadotropin was given, four or five injections of 6,000 international units Here the excretion of estrogens does not rise distinctly until large doses of serum gonadotropin are given, 1 600 to 3,200 international units The following treatment with chorionic gonadotropin produces an additional rise in the excretion of estrogens in the

16 Venning E M Further Studies on Estimation of Small Amounts of Sodium Pregnandiol Glucuronide in Urine J Biol Chem 126: 595-602 (Dec) 1938

17 Memorandum on the International Standard for the Gonadotropic Substance of Pregnant Mares Serum Bull Health Organ League of Nations 8 898-900 1939 Memorandum on the International Standard for the Gonadotropic Substance of Human Urine of Pregnancy Chorionic Gonadotropin Bull Health Organ, League of Nations 8 884-886, 1939

first case, the other case shows at this moment a secondary rise in the excretion of estrogens after a fall coincident with the last injections of serum gonadotropin. In both cases there was bleeding from the mucosa at the stage of secretion a few days after the discontinuance of the treatment with chorionic gonado-

Chart 7—Case of amenorrhea treated with serum and chorionic gonadotropins

tropin. The results indicate that in stimulating treatment with serum gonadotropin the dose should not be less than about 2,000 to 3,000 international units per injection and that several such injections should be given in succession. As far as may be judged from the present cases, this form of treatment is folhcle stimulating, but, as will be pointed out later, the treatment with serum gonadotropin is not sufficient to produce the complete ovarian cycle.

Chart 5 shows about the same results. In this instance a pause of some days was made between the three series of injections of serum gonadotropin, each of five injections. After the last injection of serum gonadotropin chorionic gonadotropin was given in the usual manner. A distinct rise in the excretion of estrogens was first demonstrated at the beginning of chorionic gonadotropin therapy, the rise most likely in the beginning, however, being due to the serum gonadotropin therapy. The combined treatment was followed by menstruation.

In the case presented in chart 6 the treatment was carried out after the following plan. Serum gonadotropin was given first in doses of about half the usual size, and this treatment was followed immediately by four injections of chorionic gonadotropin of 3,000 international units. This treatment gave neither any rise in the excretion of

Chart 8—Case of amenorrhea treated with serum and chorionic gonadotropins

estrogens nor any bleeding. After a pause of one month the patient was given a new series of serum plus chorionic gonadotropin, and this time the doses of both preparations were doubled. The last series of injections brought about both a rise in the excretion of estrogens and menstruation. This case confirms the view that in the serum gonadotropin therapy the dose should be at least 2,000 to 3,000 interna-

tional units per injection. It is to be emphasized that the negative result of the first treatment in this case is not due to insufficiency of chorionic gonadotropin dosage, for we have found that after treatment with sufficient doses of serum gonadotropin an adequate response to injections of chorionic gonadotropin is obtained regularly when considerably smaller doses are given than those employed here. The question about the proper dosage of chorionic gonadotropin will be dealt with later. In these cases the main object was to find a suitable administration of serum gonadotropin in the combined therapy. The cited cases show, then, that five consecutive injections of 3,000 international units of serum gonadotropin seem to constitute a rational procedure when the aim is to stimulate the follicular activity in cases of failing or lowered ovarian function.

Chart 7 illustrates a therapeutic experiment in a case of amenorrhea in which the output of estrogens prior to the treatment kept at an entirely normal level. Here we commenced with chorionic gonadotropin therapy alone—which perhaps would seem quite rational in such a case—since according to experimental studies on man and animals the chorionic hormone should act particularly as a luteinizing agent. In this case, however, no effect was obtained with chorionic gonadotropin alone, although the doses here employed as will be shown later have proved sufficiently large when this treatment is preceded by injections of serum

Chart 9—Excretion of estrogens and pregnandiol in the urine in a case of amenorrhea treated with serum and chorionic gonadotropins

gonadotropin. The usual combined treatment resulted in an enormous rise in the output of estrogens and menstruation. Naturally this experiment may be interpreted in various ways but at any rate it illustrates clearly the effectivity of the combined treatment.

Chart 8 presents a therapeutic experiment in which serum and chorionic gonadotropin first were given together, without any distinct effect. Then the usual successive treatment with the two preparations was given and resulted in an increased excretion of estrogens and menstruation.

This sort of experiment might indeed be varied with differing dosages, but we did not consider it likely to result in any advance.

As mentioned in the introductory remarks, some authors have made observations indicating a possible luteinizing effect of the serum gonadotropin on the human ovary. This effect if constant, would mean that this principle alone would be sufficient to produce a complete ovarian cycle and that the following chorionic gonadotropin therapy thus would not be required.

In order to see whether treatment with serum gonadotropin alone might possibly be able to replace our combined method, we gave 4 patients a preliminary treatment with 16,000 international units of serum gonadotropin, and after a pause of two weeks or a little longer we gave them our usual combined treatment, commencing with the same number of injections

of serum gonadotropin in the same doses as before and continuing with the administration of 30,000 international units of chorionic gonadotropin. During this treatment we have followed the excretion of estrogens in the urine and have also determined the output of pregnandiol. The presence of pregnandiol in the urine shows that corpus luteum is formed. The absence of pregnandiol does not perhaps indicate with absolute certainty that corpus luteum is not formed, as according to our experiences it is difficult with accuracy to determine the small amounts of this substance that correspond to the normal cycle. From charts 9 to 12, however, it is evident that the appearance of the bleedings, the condition of the endometrium and the amount of pregnandiol demonstrated in the urine clearly show the difference in the effect of serum gonadotropin alone and of serum and chorionic gonadotropins combined.

Explanation of the Signs in Charts 9 to 12—As in the preceding charts the stepped curve gives the output of estrogens per day in mouse units. The unbroken line on the abscissa indicates that the excretion of pregnandiol was assayed but pregnandiol was not present in any measurable amount. The black rectangular areas on the abscissa give the output of pregnandiol in milligrams per day.

Chart 9 illustrates a therapeutic experiment after the plan already given. The serum gonadotropin ther-

Chart 9.—Excretion of estrogens and pregnandiol in the urine in a case of amenorrhea treated with serum and chorionic gonadotropins

apy produced a minor rise in the excretion of estrogens but no bleeding or any measurable output of pregnandiol. Treatment with serum and chorionic gonadotropins was followed by a greater excretion of estrogens, and a considerable amount of pregnandiol was found in the urine during and after the injections of chorionic gonadotropin, a few days later menstruation appeared.

Chart 10 illustrates the treatment in a case after the same lines as given in chart 9. The reaction is essentially the same.

In chart 11 a similar effect is seen with regard to the excretion of estrogens and pregnandiol. In this case there was a little bleeding after the serum gonadotropin therapy, but a specimen of the endometrium showed this to be in the proliferative phase, though exhibiting slight cystic hyperplastic changes. After the combined treatment a new bleeding appeared, and this time the mucous membrane was in the premenstrual phase.

In the experiment portrayed in chart 12 a trace of pregnandiol could be demonstrated in the urine after the first series of injections of serum gonadotropin alone. The appearance of bleeding at this time caused a specimen of the endometrium to be taken; this was found to be in the proliferative stage and showed no sign of secretion. The demonstrated trace of pregnandiol allows of no definite conclusion. Perhaps there was a beginning luteinization but at any rate this has

not been sufficient to bring the endometrium into the secretory phase. The subsequent combined therapy had the typical effect.

In recapitulation of the experiences from the therapeutic experiments here described—to which could be added a long series of cases confirming the results

Chart 11.—Excretion of estrogens and pregnandiol in the urine in a case of amenorrhea treated with serum and chorionic gonadotropins

reported—it may be said that an adequate stimulation of the human ovary, by inhibited function, to an activity similar to the normal spontaneous process, i. e., beginning with follicular stimulation and going on to luteinization, is best obtained by a combined treatment commencing with serum gonadotropin and continuing with chorionic gonadotropin. We found the suitable dosage of serum gonadotropin to be about 3,000 international units daily for some days in succession—for instance, five days. Then chorionic gonadotropin is to be employed.

It now remains to look into the dosage of chorionic hormone required for the production of luteinization as the therapeutic experiments reported tell nothing about the minimal dose of chorionic gonadotropin that with reasonable regularity produces luteinization after a preceding treatment with serum gonadotropin.

In order to elucidate this question, we have treated a series of patients first with the dose of serum gonadotropin (3,000 international units \times 5) we found suitable according to the preceding experiments and then

Chart 12.—Excretion of estrogens and pregnandiol in the urine in a case of amenorrhea treated with serum and chorionic gonadotropins

with chorionic gonadotropin in different doses, as recorded in the accompanying table.

The first column gives the number of reactors, i. e., patients responding to the treatment with a distinct increase in output of estrogens. In this table we have included only such reactors, leaving out a small number of patients who proved quite refractory to the stimulation with gonadotropic substances. Since the

question looked into here is the proper dosage of chorionic gonadotropin required for the production of luteinization after a preceding adequate follicular stimulation with serum gonadotropin, the entirely refractory cases have to be left out of consideration.

As will be seen from the table, any dosage of serum gonadotropin under 1,500 international units $\times 3$ is undoubtedly inadequate. With this chorionic gonadotropin dosage of 1,500 international units $\times 3$ we obtained a complete reaction (i. e., bleeding from a mucous membrane in typical premenstrual phase) in 10 out of 12 cases. In 1 case bleeding was obtained but the mucous membrane was not of the premenstrual type, and in another case no bleeding appeared but a definite excretion of pregnandiol has to be looked on as indicating that luteinization has taken place.

We stopped at the last dosage, and the method for administration of gonadotropic substance we thus have arrived at is as follows:

Serum gonadotropin, 3,000 international units daily for five consecutive days, then chorionic gonadotropin

Reaction of Amenorrheic Patients on Various Doses of Chorionic Gonadotropin Given After Preliminary Treatment with Serum Gonadotropin (3,000 International Units $\times 5$)

	Number of Reactors	No. Bleeding	Bleeding but Mucosa Not in Premenstrual Phase	Bleeding, Premenstrual Mucosa
1 Chorionic gonadotropin 3×100 international units after preceding treatment with serum gonadotropin	5	1	4 (1 in secretion but not premenstrual 3 without signs of secretion)	0
2 Chorionic gonadotropin 3×250 international units after preceding treatment with serum gonadotropin	7	2	5	2
3 Chorionic gonadotropin 3×500 international units after preceding treatment with serum gonadotropin	10	2	8 (1 in secretion but not premenstrual 4 without signs of secretion)	3
4 Chorionic gonadotropin $3 \times 1,500$ international units after preceding treatment with serum gonadotropin	12	1 (Preg nandiol +)	1 (Preg nandiol 0)	10

1,500 international units every other day, three times in all.

The menstruation usually appears about ten days after the last injection of chorionic gonadotropin.

The last two graphs, charts 13 and 14, illustrate a couple of cases in which this dosage was employed.

COMMENT

It would fall outside the scope of this paper to discuss in detail the clinical questions connected with the therapeutic employment of gonadotropic substances.

Here it is merely to be mentioned that with this method we have been able to produce menstruation in a greater majority of our patients with secondary amenorrhea and in some patients with primary amenorrhea, and that, according to our present experiences, about one half of the patients treated in this way have continued menstruating after the treatment. We have now seen many instances of striking, truly favorable therapeutic results—for instance, pregnancy in 2 cases of primary amenorrhea and continued regular menstruation in many cases of secondary amenorrhea, also some instances of pregnancy after the treatment of secondary amenorrhea.

The treatment may give some untoward effects, the most important of which is the not altogether infrequent production of a considerable swelling of one of the ovaries or of both. The patient may then have a sensation of tension or of pain in the abdomen, and on palpation the ovary is found to be enlarged, so that

it may even rise from the pelvis like ovarian cysts. Usually no great inconvenience results from this complication, the patient has to keep to her bed for a few days and then this reaction subsides rapidly. In 1 case we were able during a laparotomy to as-

Chart 13—Course of a case of amenorrhea treated with serum plus chorionic gonadotropins as given in the text.

certain that it was a matter of lutein tumors. In this case there was an unusually strong abdominal reaction, and since we were not familiar with this effect of the treatment we thought that there were indications for the performance of a laparotomy.

A transitory rise in temperature is not infrequent. Serum gonadotropin is less active in this respect, but chorionic gonadotropin gives not infrequently a brief elevation of the temperature to 38-39°C (100.4-102.2°F).

The undesirable effects mentioned have not been so bad as to keep us from giving ambulatory treatment in a good many cases. The ovarian reaction just mentioned has to be kept in mind, however, as such a lutein tumor and the resulting symptoms may easily be mistaken for other morbid conditions, and patients with any severe degree of such a reaction have to be confined to bed for some days.

SUMMARY

In cases of failing ovarian function in women, the gonadotropic preparations can produce an adequate reaction in the ovary followed by menstruation. By a suitable dosage it is practicable in most cases of secondary amenorrhea to set the ovarian function going at least temporarily and often permanently.

It was found most expedient to treat the patients first with serum gonadotropin and afterward with chorionic gonadotropin.

Experimental studies led to a rational dosage and a standard method for this stimulation therapy. Intramuscular injection of 3,000 international units of serum gonadotropin is given daily for five consecutive days and then 1,500 international units of chorionic gonadotropin is given every day, three times in all.

In reacting patients the menstruation makes its appearance about ten days after the last injection.

ADJUNCTIVE THERAPY WITH DIETHYL-
STILBESTROL IN OBSTETRICS
AND GYNECOLOGY

CRITICAL EVALUATION

A R ABARBANEL, M D
WASHINGTON, D C

HARRY ARANOW, M D

AND

MILTON J GOODFRIEND, M D
NEW YORK

Before proceeding to evaluate the present status of diethylstilbestrol in clinical obstetrics and gynecology, let us observe where diethylstilbestrol fits into our therapeutic philosophy by briefly reviewing certain significant trends in reproductive physiology, especially as regards our conception of the so-called "sex" hormones estradiol progesterone and testosterone. The guiding principle in these recent advances has been the premise that all biologic processes are essentially chemical in nature.

Basic in its significance was the demonstration that the steroid nucleus is not essential for gynecologic activity, because its implications are so broad and sweeping. In a series of investigations that forms one of the most fascinating chapters in modern medical annals, Dodds¹ and his co-workers chemically dissected the steroid skeleton of estradiol in a search for the chemical moiety requisite for gynecogenic activity. Among the scores of nonsteroidal chemical substances evolved, a very potent gynecogen was discovered in 4-4'-diethyl-dihydroxy-stilbene, popularly known as stilbestrol, but for which the designation diethylstilbestrol, recommended by the Council on Pharmacy and Chemistry of the American Medical Association, will be used throughout this report. Pharmacologically, diethylstilbestrol is essentially similar to estradiol in every important respect but one. Diethylstilbestrol loses little of its potency when administered orally, because unlike estradiol, it is not inactivated by the liver.²

Important also have been the findings of the biologist that each of these so-called sex hormones, as well as diethylstilbestrol, possesses bisexual properties.³ Since not one of them is specific for either sex, one can no longer logically retain such terms as "male sex hormone" or "female sex hormone" for by definition,

such entities do not exist.⁴ Each exerts both androgenic and gynecogenic activity.⁵

Equally significant have been the contributions of the physiologist and pharmacologist in showing that these so-called sex hormones as well as diethylstilbestrol may materially influence many diversified phases of the body economy of both the male and the female independent of any effects on the secondary sexual apparatus.⁶ In short so great is the weight of the evidence that no one can any longer consider the genital tract as a periscope with which to view the extragenital effects of diethylstilbestrol, estradiol progesterone or testosterone. Rather, one must recognize that these chemical substances possess multiple constitutional activities that are not dependent on their effects on the secondary sex organs.

In review, then, it is noted that the nonsteroidal chemical substance diethylstilbestrol is a constitutional drug. In its influence on the secondary sexual apparatus it exhibits bisexual activity although its properties are preponderantly gynecogenic. Since the latter were the first to be recognized, diethylstilbestrol at present has found its widest use in clinical obstetrics and gynecology, especially since it is efficacious orally as well as relatively inexpensive. Growing recognition of its multiple constitutional effects, however, has brought about its introduction in several other fields such as internal medicine otorhinolaryngology, dermatology and dentistry.

Now let us note where diethylstilbestrol fits into our general plan of therapy. An adequate therapeutic regimen must include treatment of the entire patient the sum of her mental as well as physical ills, be they real or imaginary. Treatment has to be individualized because each patient presents problems peculiar to herself. Furthermore, gynecic endocrinopathies in their basic concept represent disturbances in the metabolism of the endocrine glands themselves or of the recipient organs or both. Since each patient is the metabolic sum of what she eats and drinks, it becomes clear why diet and thyroid are of fundamental importance in gynecic endocrine therapy. A diet to be adequate must not only be properly balanced but also be properly cooked so as to preserve the essential vitamins and minerals.⁷ Caloric intake in comparison is of secondary importance.⁸ Thyroid exerts a profound stimulating influence on the general metabolic functions of the organism.⁹

Equally important in the management of the patient is mental readjustment and reassurance. The physician must sweep away the cranial cobwebs spun by the spiders of folklore and superstition especially with

⁵ The description of the action of any one of the chemical substances must be based on the specific effect of a particular substance on an individual and organ under a definite set of circumstances and then compared to what has been set up as the norm for maleness and for femaleness. If under these conditions the action is exerted in the direction of maleness it is called androgenic while if it is in the direction of femaleness it is called gynecogenic. The gynecogens are further subdivided into estrogens which bring about proliferative changes in the secondary sexual apparatus and progestogens which cause maturation or progestational changes.

⁹ If the patient proves sensitive to thyroid 10 to 15 drops of compound solution of iodine (Lugol's solution) or saturated solution of potassium iodide administered concurrently with the thyroid frequently helps offset the side effects.

regard to disorders of menstruation and their influence on sex. In addition, a critical analysis and adjustment of psychogenic factors deriving from marital, social or economic causes may often be essential for a successful therapeutic result.

A complete physical examination should always be performed by a competent internist preliminary to a thorough gynecologic examination which includes a speculum examination of the cervix. These should be repeated at frequent intervals.

Clearly, then, in the light of these considerations diethylstilbestrol, being but a single drug, can comprise just one adjunctive portion of a rational therapeutic regimen.

Proceeding on the general plan of therapy just outlined, the present status of the adjunctive use of diethylstilbestrol in clinical obstetrics and gynecology has been critically evaluated. This has been based mainly on our personal experience in over 700 cases (table 1).

In some individuals definite vasomotor instability may occur, noted clinically as hot flushes, sweats, chills or suffocations.¹³ Although their exact etiology has never been clearly proved, it seems that these characteristic vasomotor phenomena appear to reflect an instability of the heat regulating mechanisms of the individual.¹² Any circumstance, physical or mental, which places a stress on the peripheral heat regulating apparatus will intensify those symptoms. Adjunctive therapy with diethylstilbestrol, as well as with estradiol or testosterone, helps bring about symptomatic relief by tending to stabilize heat regulating mechanisms through their action on the peripheral vascular tree. This is accomplished, according to Reynolds and his co-workers, in part by a direct action on the blood vessels themselves and in part indirectly through the central nervous system.¹⁴

The common sense management of these patients has been adequately described by Novak¹⁵ and others.

TABLE 1—Various Conditions in Which Adjunctive Therapy with Diethylstilbestrol Was Employed

Indication	General Management	Total Treated	General Management		Evaluation of Adjunctive Use of Diethylstilbestrol
			Alone	Plus Diethylstilbestrol	
Climacteric vasomotor instability	Mental reassurance sedation, score card, diet, thyroid	45	20	25	Excellent adjunctive value
Senile vulvovaginitis (including essential senile pruritus)	Establish diagnosis, diet, thyroid, acid douches, cotton tampons	32	11	15	Excellent adjunctive value
Juvenile vulvovaginitis (gonococcal)	Establish diagnosis, hygienic regimen, sulfonamides	21	0	21	Excellent adjunctive value
Puerperal painful engorgement of breasts	Proper uplift, breast support				
Prevention		500	250	250	Excellent
Relief		100	50	50	Fairly good
Amenorrhea	Establish diagnosis, mental reassurance, diet, thyroid, repeated biopsies				Excellent as aid in correcting mental maladjustment
Secondary		47	21	15	
Primary		6	2	4	Also physical disproportion
Induction of early abortion	Medical induction, potent oxytocics	24		24	No value whatsoever
Inhibition of onset of adequate milk secretion	Baby nursing	50	25	25	Value only temporary
Suppression of established lactation	Baby nursing	50	25	25	No value (actually stimulates lactation)
Galactorrhea		6		6	No value
Induction of premature labor	Medical induction, potent oxytocics	16	10 failed	10+6=16	Results only suggestive
Missed abortion or labor	Medical induction, potent oxytocics	4	4	4	Results quite suggestive
Uterine inertia (myometrial origin)	Establish diagnosis, sedation, fluids	10	10	10	Results only suggestive
Primary dysmenorrhea	Mental readjustment, diet, thyroid, antispasmodics	21	21	21	Value very limited

In addition, we have fully utilized the extensive clinical literature as well as the personal communications of many investigators¹⁰ in forming these conclusions. The detailed management of most of the conditions to be discussed may be found in several of the recent textbooks.¹¹ The physiologic considerations on which rational therapy is based has been clearly presented and adequately correlated by Reynolds.¹²

GROUP 1 CONDITIONS IN WHICH ADJUNCTIVE THERAPY WITH DIETHYLSTILBESTROL IS OF DEFINITE VALUE

1 *Climacteric*—The climacteric may occur during or after the transition period at which reproductive function usually ceases. This phenomenon is a normal physiologic one, characteristic of the process of aging.

10 Particularly Drs. R. R. Greene, M. E. Davis, C. V. MacBryde and K. J. Karnaky.

11 Novak, Emil. *Gynecology and Female Endocrinology*. Boston: Little Brown & Co., 1941. Mazer, Charles and Israel, S. L. *Diagnosis and Treatment of Menstrual Disorders and Sterility*. Thomas, Publisher, 1939.

12 Reynolds, S. R. M. *Physiology of the Uterus with Clinical Correlations*. New York: Paul B. Hoeber, Inc., 1939.

Certain points require added emphasis. Mental reassurance is of primary and paramount importance, for it is well established that the vasomotor phenomena of the climacteric may be deeply influenced by the patient's own psyche.¹⁴ Accordingly, at the very first visit an attempt should be made to evaluate the entire patient, mentally as well as physically. Once the diagnosis is established, a frank discussion with the patient of her condition is essential in securing her complete confidence and cooperation as well as in ridding her of many erroneous apprehensions regarding the cessation of menstruation.

In addition, she is instructed to keep a daily written record noting separately the number of flushes observed during the day and the number experienced after retiring at night. Supportive treatment includes a well

balanced diet⁷ and the use of thyroid, especially if she is obese or tired and listless. Since bromides, in our experience, have proved far more effectual than barbiturates, 15 grains (1 Gm) of triple bromides are prescribed three or four times daily. The patient is seen two weeks later. Her response may be evaluated from her story as well as from her "score card." If she has had no flushes at all during the night, the menopausal syndrome may be considered as mild or else the flushes probably stem from some psychogenic problem. Further careful sympathetic questioning should reveal the cause. If the patient is progressing satisfactorily, therapy is continued. In this manner it was found possible to control almost 50 per cent of over 400 menopausal patients. In other words, a little over 50 per cent (221 cases) required further adjunctive therapy with diethylstilbestrol.

The initial daily dose of oral diethylstilbestrol should range from 0.1 to 0.25 mg and only enough to last two weeks should be prescribed.¹⁶ Some investigators¹⁷ prefer to start with a larger dose (1 mg), but this is neither desirable nor necessary.¹⁸ It is better to adjust the dose to the patient than the patient to a certain dosage. Depending on her response, the dose level may be maintained or increased by doubling the initial dose. The patient should then be seen at two week intervals and the dose level adjusted until she is in good equilibrium, that is to say, she is having no flushes at night and only an occasional one during the day. The dosage required to achieve equilibrium is maintained for a month or so before it is gradually lowered. The patient should be kept in equilibrium for a minimum of three to six months or more before discontinuing diethylstilbestrol in order to reduce the possibility of a recurrence of symptoms to a minimum. Under this regimen satisfactory relief was secured in over 92 per cent of our cases.

For patients still menstruating at more or less regular intervals, the daily oral dose should not exceed 0.5 mg if troublesome bleeding is to be avoided. If 0.5 mg is insufficient, it is expedient to add 10 to 20 mg of oral methyl testosterone daily to the therapeutic regimen or else use this steroid alone. On the other hand, if a patient begins to bleed after an amenorrhea of one year or more a diagnostic biopsy or curettage should be done to rule out possible cancer.

In a very small minority it may be found necessary to give diethylstilbestrol by injection. Sesame oil should be the vehicle of choice. The initial dose should range from 0.2 to 0.5 mg weekly.

Occasionally it may be necessary to employ the subcutaneous injection of a 10 mg pellet of crystalline diethylstilbestrol. Before this is done, however, the patient must first show a satisfactory response to oral diethylstilbestrol. The pellet form of therapy yields the smoothest and best results per unit weight of any method of administration we have tried.¹⁶

2 Essential Senile Vulvovaginitis, Including Essential Senile Pruritus—Since this syndrome is a part of the process of aging of the individual, the entire patient must be treated not just one of her symptoms. Other constitutional and local causes must be excluded. Supportive treatment includes a well balanced, properly cooked diet, rich in vitamins and minerals, as well as small doses of desiccated thyroid. At first the patient is instructed to douche twice daily while lying flat on her back in the bathtub, using 2 quarts of a lukewarm solution containing 3 to 4 ounces of ordinary household vinegar.

If relief is not evident in two to four weeks, local therapy with an ointment containing 5 mg of diethylstilbestrol per ounce is started, as this is the most effective and efficient means of administration.¹⁹ Approximately enough ointment to contain 0.5 to 1.0 mg of diethylstilbestrol is rubbed thinly over the vulva once a day, while a small amount is smeared lightly over a vaginal cotton tampon before the latter is inserted. Acid douches are continued. When kraurosis vulvae is pronounced, it may take several months to achieve complete relief. Pelvic examinations should be performed frequently to rule out a possible damming up of secretions, such as pyocolpos or hematometria.

Uterine bleeding may occur at infrequent intervals, but it rarely is alarming. Sufficient ointment to contain 4 to 8 mg of testosterone may be substituted once or twice a day for one week out of every four. In fact, when the itching is extremely pronounced about the folds of the clitoris, testosterone ointment should be used daily, for this steroid seems to stimulate the surrounding glands to produce an oily secretion which serves to relieve the dry itching skin.²⁰

3 Juvenile (Gonococcal) Vulvovaginitis—After the diagnosis has been made by smear or culture, the mother is given careful detailed instructions regarding proper hygienic care of the child. A suppository containing 0.1 mg of diethylstilbestrol is inserted vaginally each night. If the child strongly resents this method of administration, 0.1 mg of oral diethylstilbestrol may be given one to three times daily. By watching the weekly progress of the disease, the dosage may be maintained or raised. Sulfonamides may be included in the therapeutic regimen. Once the smears or cultures are negative for three consecutive weeks, diethylstilbestrol may be discontinued, although the child should receive a monthly checkup for at least six months.²¹

4 Painful Engorgement of the Breasts in the Puerperium—This syndrome results from lymphatic and venous stasis, not from distention of the ducts with the milk.²² By what means diethylstilbestrol may prevent or relieve this condition cannot be explained on the basis of our present day knowledge.²³ That it is not

by inhibition of lactation has been clearly proved.²⁴ As a matter of fact, diethylstilbestrol, by stimulating a definitely increased production of lactogenic hormone by the anterior pituitary, actually promotes lactation.²³

The management of painful engorgement resolves itself into two phases (1) prevention and (2) relief after it comes on.²² Every puerperal patient should be fitted with an adequate uplift breast binder that raises each breast up and medial toward the opposite shoulder. It must fit snugly at the base and be very loose across the axillary portion of the breast. An old uplift brassiere or a proper nursing brassiere usually is quite satisfactory.

Prevention (in nonnursing mothers) An adequate uplift breast support is first adjusted on the patient. On the day of delivery, 10 mg of oral diethylstilbestrol is given followed by 5 mg daily for three to five days, then 3 mg daily for three days and finally 1 mg daily for three to six days. By spreading the dose schedule out over a period of about two weeks while gradually decreasing the dosage, the incidence of delayed filling of the breasts may be considerably reduced. If therapy is not started within forty-eight hours after delivery, the initial dose should be 25 mg. Delayed filling of the breasts may occur some two to twelve or more days later. As a rule it is transitory and painless, while secretion is usually slight and watery.²² In the manner just outlined, good results were secured in close to 90 per cent of our patients.

Prevention in the Nursing Mother (especially primiparas) Beginning right after delivery, 5 mg of diethylstilbestrol is given daily for three to five days. Since actual milk secretion does not usually occur until the third or fourth day post partum, it is an excellent idea not to put the baby to breast until then, thus preventing many a cracked or fissured nipple. Adequate milk secretion will occur if the baby continues to nurse vigorously.²²

Prevention After Weaning After an adequate uplift breast support has been applied, the patient is given 25 mg of diethylstilbestrol orally. The next day 10 mg is administered, followed by 5 mg daily for the next three days.

Relief of Painful Engorgement After Its Onset Here a few milligrams of prevention would have been worth several kilograms of cure. After an adequate uplift breast binder is applied, 25 to 50 mg of diethylstilbestrol is given orally. Relief may be apparent in eighteen to twenty-four hours in about 65 per cent. The next day 10 mg is administered orally, followed by 5 mg daily for three days. In about 25 per cent secondary filling may occur, while a watery secretion may persist for several days or even weeks. In contrast, when 10 to 25 mg of testosterone propionate is given by injection, or 100 mg of methyl testosterone is given orally, relief is usually apparent in two to twelve hours in close to 90 per cent, while secondary filling is rarely, if ever, noted.²⁵

5 Secondary Amenorrhea—After establishing a working diagnosis of functional amenorrhea, one should secure a complete blood count, a urinalysis, the basal metabolic rate and an endometrial biopsy. An ade-

quate and properly cooked diet is prescribed together with desiccated thyroid. A thorough endometrial suction biopsy, performed regularly every four to five weeks, serves as a stimulative as well as a diagnostic measure.

If, after three to six or more months, the menses have not returned, a frank talk with the patient is in order. It must be emphasized that lack of menses does not make her one whit less a normal woman nor does it signify that she has become a sexless creature. If the mental maladjustment to the amenorrhea is still not corrected, diethylstilbestrol may be administered. (It should be noted that this may constitute just as real a symptom complex as hot flushes in the climacteric.) Many dose schedules have been recommended,²⁶ but this is the one we have found most satisfactory. Starting with 0.25 to 0.5 mg daily, the dose is gradually raised every five to seven days until 1 mg has been given daily by mouth for twenty-one days. Bleeding may occur in five to fifteen days. If not, 2 mg daily is prescribed for three weeks. With each cycle of therapy the dose may be raised by 1 or 2 mg until withdrawal bleeding does occur. After bleeding has resulted three times, the patient is given a rest for three months to note whether any improvement has occurred. If not, the patient is usually quite ready to listen to common sense and adjust herself to her amenorrhea.

6 Primary Amenorrhea—Complete evaluation of the patient and the contributing factors leading to the absence of menstruation determine the course of therapy. The principal indication for the utilization of the gynecogenic activity of diethylstilbestrol is as an aid to offset the physical and psychic maladjustments that may occur.²⁷

If the syndrome is functional in origin, a well balanced, properly cooked diet combined with the judicious use of thyroid over the space of many months is of prime importance. Cyclic administration of diethylstilbestrol as described may be used to accelerate the development of the secondary sexual characteristics. Since each patient presents problems peculiar to herself, therapy has to be individualized. In certain instances in which infantilism is pronounced, therapy may include the subcutaneous injection of a 10 mg pellet of crystalline diethylstilbestrol at two or three month intervals.²⁸ Rest periods from therapy of a month or so is advisable at regular intervals.

GROUP 2 CONDITIONS IN WHICH ADJUNCTIVE THERAPY WITH DIETHYLSTILBESTROL HAS BEEN SUGGESTED BUT THE RESULTS HAVE SHOWN DIETHYLSTILBESTROL TO BE OF LIMITED OR NO VALUE

1 Induction of Early Abortion—In 24 cases of early pregnancy in which menstruation was from one to ten weeks "overdue" and in all of which the Friedman test was positive, diethylstilbestrol was completely ineffective in interrupting the pregnancy.²⁹ The daily oral dose ranged from 5 to 100 mg for a total dosage of 50 to 500 mg. Similarly negative results have been reported with massive doses of estradiol.³⁰

2 *Inhibition of Lactation and Suppression of Established Milk Secretion*—Diethylstilbestrol will not inhibit the normal onset of lactation, although it will delay the appearance of the normal average amount of milk secretion until two to seven days after the drug is stopped, provided the baby continues to nurse.²¹ Once lactation is established, however, as much as 500 mg of diethylstilbestrol will not materially affect the amount of milk secretion.²⁴

Several reports have appeared claiming inhibition and suppression of lactation in the human being by means of diethylstilbestrol, testosterone and other steroids. Unfortunately, these investigators have not clearly differentiated the syndrome of painful engorgement from the process of lactation. Furthermore, they have failed to evaluate properly the fact that the baby was removed from the breast, a procedure which, by itself, will suppress lactation.²³

3 *Galactorrhea*—Although some investigators have reported that diethylstilbestrol will alleviate this condition, we have not been successful in a single case in a series of 6. Similar observations have been noted by others.³¹

GROUP 3 CONDITIONS IN WHICH THE ADJUVANT USE OF DIETHYLSTILBESTROL HAS SHOWN PROMISE IN PRELIMINARY CLINICAL TRIALS

1 The adjuvant use of diethylstilbestrol in the management of the induction of labor is based on its sensitizing or priming action on the uterine muscle to the subsequent action of potent oxytocics. The usual indication is a toxemia of pregnancy that is not responding to conservative treatment. The patient is given 150 to 200 mg of oral diethylstilbestrol in divided doses, usually 15 to 20 mg in ten hourly doses. The next morning the patient receives a medical induction followed by small doses of a potent solution of posterior pituitary. The details have been described elsewhere.²⁰ Diethylstilbestrol alone is ineffectual, it must be followed by a potent oxytocic in order that labor may ensue.²⁹ Regardless of the type of induction used, it is felt that the preliminary priming of the uterus with diethylstilbestrol helps to insure a successful outcome. Of 16 carefully chosen cases, 12 were successful, including 7 in which a previous medical induction followed by potent oxytocics had been unsuccessful.

2 In missed abortion or missed labor the fetus dies but fails to be expelled. In the majority of cases the estrogen level becomes low or disappears.³⁰ By priming the myometrium with diethylstilbestrol, the uterine muscle becomes sensitized to the subsequent action of oxytocics. The management of missed abortion or labor is the same as that outlined for the induction of labor.²⁹

3 Uterine inertia may result from myometrial dystonia. Uterine contractions are ineffectual.

Supportive measures must be fully adequate after the diagnosis has been established. Oral diethylstilbestrol in doses of 25 to 50 mg at one or two hour intervals for four to six doses may yield a successful result in about two thirds of the cases.²⁰ If labor ceases, the procedure outlined for the induction of labor may be used. Excellent responses were noted in 7 out of 10 carefully chosen patients.

4 Adjunctive therapy with diethylstilbestrol in the prophylaxis of postpartum and postabortal infections appears to offer great promise in the light of the published reports²² and our own limited experience.

In addition to the indicated supportive measures, where infection seems most likely to ensue, such as after a criminal abortion or a difficult operative delivery from below, 5 mg of oral diethylstilbestrol is given twice on the day of delivery, then once daily for five to ten days. If an endometritis is already present 25 mg is given, followed by 5 mg daily. Oxytocics are administered daily.

GROUP 4

Diethylstilbestrol has been recommended as an aid in the management of several other conditions, but the number of available clinical reports, as well as our own experience, is insufficient for adequate evaluation. These include dysmenorrhea,³³ functional uterine bleeding,³⁴ nonpatent or stenosed fallopian tubes,³⁵ threatened abortion,³⁶ and prevention of pregnancy accidents in diabetes.³⁷ Further clinical trials are essential for the proper evaluation of adjuvant therapy with diethylstilbestrol in these conditions.

In primary dysmenorrhea, diethylstilbestrol has been recommended for such reasons as inhibition of ovulation on the one hand and stimulation of a hypofunctioning corpus luteum on the other.³³ In our experience, clinical trials with diethylstilbestrol have been very disappointing. Out of 21 cases, complete relief was achieved in 2 and partial relief in 5. In all 7 however, it was only temporary. In addition in 3 of the remainder premenstrual breast pain was definitely accentuated, while in 2 others premenstrual irritability was definitely aggravated. One of our patients became pregnant during treatment. It turned out to be an ectopic pregnancy. The available clinical reports are too scanty for evaluation.

In the prevention of pregnancy accidents in diabetic patients the value of diethylstilbestrol is still not settled.³⁷ In treated cases White claims a salvage of 90 per cent of the babies compared to 35 per cent in untreated cases.³⁸

SIDE REACTIONS

Review of the early clinical reports on the incidence of side reactions to diethylstilbestrol revealed a great disparity.⁴⁰ Careful studies since then, however, have served to clarify the situation. The consensus is that, when diethylstilbestrol is compared on a potency basis or even on a weight basis with estradiol or estrone,

the toxic effects are similar in the experimental animal⁴⁰ Detailed systematic studies in the human being have failed to reveal any true toxicity⁴¹

Clinically, the most common side reaction encountered is nausea, especially with menopausal patients. Careful study of these patients has brought to light several important factors, each of which must be carefully evaluated. The dose level is of prime importance (table 2). A few years ago it was reported from this clinic that the higher the dosage the greater was the incidence of side reactions.¹⁶ This has been amply confirmed.⁴² Moreover, it has been found that in evaluating the incidence of side reactions the relative estrogenic potency of the substance in question must also be taken into consideration.⁴³

Equally important in evaluating nausea is the patient herself.⁴⁴ Analysis of the latter reveals that two broad groups are recognizable. The first group is composed of patients in whom nausea may be considered as being incidental in nature. It includes those who are unable to take any type of oral medication including placebos, as well as those who become nauseated only when simultaneously receiving some other medication which by itself could produce nausea, such as intravenous neosphenamine, digitalis or ferric ammonium citrate.

TABLE 2—Relationship of Daily Oral Dose of Diethylstilbestrol to Incidence of True Gastrointestinal Side Reactions in Climacteric Patients. The Higher the Dose Level the Greater the Incidence of Nausea

Dose (Mg.)	Nausea (Per Cent on Dose)
0.10	13
0.25	34
0.50	53
1.0	129
5.0	417

This group also embraces those patients who become nauseous with their flushes, for not infrequently the flushes may be accentuated at the start of treatment, thus aggravating the nausea. The nausea disappears as the flushes are relieved. These women are particularly liable to be nauseous on arising, a sort of "morning sickness" of the climacteric.

The second group comprises those patients in whom the nausea may be considered as a true side reaction. In this group the incidence of nausea is clearly related to the dose level (table 2). Further study disclosed that patients with a previous past history of sensitivity to fried and fatty foods are much more prone to develop nausea at a given dose level than those with a previously negative gastrointestinal history. This was shown to be statistically significant.⁴⁴

Just why patients with a suggestive "gallbladder syndrome" are so much more likely to develop nausea when receiving diethylstilbestrol or estradiol remains to be clarified. It has been reported that estrogen may bring about a delay in the emptying time of the gallbladder.⁴⁵ Such an effect, if confirmed in the human being, would serve to explain the increased nausea in the "gallbladder syndrome" patients, for they would tend to be more sensitive.

The management of these patients should include administration of cholagogues. Two teaspoons of magnesium sulfate once or twice a day are usually effective without causing cramping or diarrhea. Mild mercurous chloride, crude bile salts or purified bile acids may also be used. The nausea experienced by patients with a previously negative gastrointestinal history does not usually present much difficulty. Its incidence may be considerably reduced by starting with a small dose level, 0.1 to 0.25 mg, and then raising it gradually if necessary. Administration of cholagogues is also helpful. With the majority of these patients the nausea is usually transient, disappearing in spite of continued treatment.

A word should be said about dosage. One mg of oral diethylstilbestrol daily is approximately equivalent to injecting either 1 mg of estrone (theelin) daily or 1 mg of estradiol benzoate about every third day. Clearly, then, a daily dose of 1 mg is a relatively large dose especially when it is recalled that, in contrast to estradiol and estrone, stilbestrol is not inactivated by the liver. Consequently a much higher amount of active estrogenic substance is available to the body. Furthermore, it takes from three to as much as twelve days for the human being to excrete a given dose of diethylstilbestrol in contrast to the two or three days required for estradiol and estrone.⁴⁶ In short, a cumulative effect occurs, so that even 0.1 mg daily of oral diethylstilbestrol is not such a small dose after all.

Regarding the possible carcinogenic action of diethylstilbestrol in the human being, the discussion can best be summarized as follows. According to Geschickter, the mammary cancers induced in rats by injection of estrogenic substances are due to the physiologic changes produced rather than to the carcinogenic nature of the chemical used.⁴⁷ Further, Novak,⁴⁸ in presenting the clinical phase of the problem, succinctly concluded that "it would be carrying conservation to an extreme to deprive the menopausal patient of proper estrogen therapy merely on the basis of this slight theoretical possibility."

SUMMARY AND CONCLUSIONS

Diethylstilbestrol, a nonsteroidal chemical substance, is actually a constitutional drug, possessing, among other properties, potent gynecogenic activity. The latter attribute, plus the fact that diethylstilbestrol is therapeutically efficacious orally as well as inexpensive, is the cause of its widespread use in the management of certain gynecic conditions.

Diethylstilbestrol, being but a single drug, can logically comprise just one adjunctive part of a rational therapeutic regimen. The latter, in order to be ade-

quate, necessitates treatment of the total patient, the sum of her mental as well as her physical ills

In the general management of a patient with one of the following conditions, adjunctive therapy with diethylstilbestrol may be of definite value (a) severe climacteric vasomotor instability, (b) essential senile vulvovaginitis including generalized essential senile pruritus, (c) juvenile vulvovaginitis, (d) prevention or relief of puerperal painful engorgement of the breasts and (e) amenorrhea, secondary or primary

The adjuvant use of diethylstilbestrol is of no value whatever in the general management of the following conditions (a) induction of early abortion, (b) suppression of lactation and (c) galactorrhea

In the management of primary dysmenorrhea, adjunctive therapy with diethylstilbestrol is of very limited value

Analysis of gastrointestinal side reactions to diethylstilbestrol, especially in climacteric patients, reveals the following (a) The higher the dose level the greater the incidence of nausea (b) The relative estrogenic potency of the substance in question must be considered in evaluating side reactions (c) Nausea may be an incidental or a true side reaction, depending on the patient (d) Patients with a previous history of sensitivity to fried and fatty foods are much more prone to develop nausea at any given dose level than those with a previously negative gastrointestinal history (e) The pregnant and puerperal patient, including those with a pronounced toxemia and even eclampsia, with evident cardiorenal and hepatic damage, may easily handle as much as 250 mg of oral diethylstilbestrol a day without evident side effects

ABSTRACT OF DISCUSSION

DR EMIL NOVIK, Baltimore The fact that a new hormonal chemical substance like diethylstilbestrol can produce the biologic effects formerly attributed only to the intrinsic vital principles which we recognize as hormones must have been startling to many but it has been established beyond a doubt. If there is any criticism of this paper it is that, for the sake of completeness the authors have included a discussion of many indications for the use of the drug which are of questionable value. Those of importance are those included in table I, embracing especially menopausal symptoms, the gonorrheal vulvovaginitis of children and senile vaginitis. The authors properly stress the inadequacies of diethylstilbestrol in the treatment of amenorrhea while many of us may feel that the problem of painful engorgement of the breasts is not as frequently important as their discussion might indicate and that very simple measures will often make patients comfortable. After a number of years of clinical and laboratory study it seems definitely established that the unpleasant toxic effects discussed in the paper are never of serious import to the patient. Moreover, when the dosage is very conservative the incidence of these side effects is probably not over 10 per cent, and certainly nothing like the 80 per cent which some authors have reported in the past. By far the most frequent indication for diethylstilbestrol is in the treatment of menopausal vasomotor symptoms when these are troublesome enough to call for direct treatment. In my judgment diethylstilbestrol has been a genuine boon for this indication making unnecessary in most cases the long continued and expensive hypodermic medication on which we formerly relied. We have all seen 'estrogen addicts' created by the automatic resort to 'shots' at stated intervals regardless of whether or not the symptoms justify any medication. For similar reasons no woman should be started on diethylstilbestrol therapy in any routine fashion for an indefinite period. In few indications is individualization of treatment more important than in the management of the menopause.

DR ROBERT B GREENBLATT, Augusta, Ga The authors have pointed out the clinical indications of diethylstilbestrol therapy. I agree with them in principle. There is one point with which I take issue namely the contention that diethylstilbestrol is not of value in the suppression of lactation. In my experience diethylstilbestrol has been as effective as the gonadal steroids. Androgens and estrogens are capable of limiting the amount of lactation by preventing release of the lactogenic hormone from the hypophysis, they do not necessarily suppress it. If the sucking reflex is removed, lactation will stop by itself and so diethylstilbestrol may be used temporarily to limit milk production while the nursing infant is taken away from the mother's breast. One indication for diethylstilbestrol worth stressing is its use in dysmenorrhea. Steroid hormones are expensive and the average patient cannot afford the use of such hormones as estradiol benzoate and testosterone propionate. In selected cases diethylstilbestrol in vaginal suppository form in 0.2 to 0.5 mg dosage may be administered vaginally during the intermenstruum, and the dysmenorrhea will be alleviated in about 60 per cent of the cycles. Since diethylstilbestrol is relatively cheap, it is a boon to those who cannot afford expensive therapy. Toxic reactions are frequently observed with the oral doses formerly advocated. However when other forms of medication are used, effective results may be obtained with minimal side reactions. The percutaneous use of diethylstilbestrol in an alcohol vehicle diethylstilbestrol dissolved in alcohol for oral use, or particularly diethylstilbestrol employed vaginally as a suppository constitute effective methods which have a low incidence of toxic or side reactions. Perhaps nausea and vomiting are not entirely simple phenomena due to the action of the drug on the central nervous system. A contributing factor when oral medication is used may be the local action on the gastric mucosa. I found that when vaginal suppositories were employed, some patients complained of nausea and in addition there was vaginal soreness, indicating that the action of the drug locally was somewhat irritating. I do not feel that diethylstilbestrol is toxic in physiologic doses. Kreitmair showed that the daily administration of 1 mg per gram of body weight would kill a mouse in ten days time, but such comparatively massive doses do not constitute a priori arguments against the use of diethylstilbestrol in clinical practice. Proper dosage and not over-dosage, is the essential answer to the argument.

DR JOSEPH A HEPP, Pittsburgh I have treated 343 women with diethylstilbestrol, and toxic symptoms were noted in 6.12 per cent of these patients. Early in the use of diethylstilbestrol with menopausal patients toxic symptoms were frequently encountered. I believe I tried to obtain results too quickly. Now it seems that one can secure results with a much smaller dose. Diligence to observe overtreatment should be practiced. During an observation of thirty-four months there have been no harmful effects from the use of diethylstilbestrol. The production of uterine bleeding in postmenopausal women has frequently been mentioned by investigators in the field of estrogenic therapy. This is usually due to too much medication over a prolonged period of time. There is excessive estrogen stimulation of the endometrium. Needless to say, this bleeding is a most distressing symptom to a woman who has stopped menstruating many months or even years previously. The medication should be discontinued when this type of bleeding is encountered, and the dosage should be decreased if treatment is resumed. In our group there have been a number of patients in whom there was no effect on the systolic and diastolic blood pressure, even though definite improvement was noted in the hot flashes. This absence of effect on the hypertension was observed in the physiologic menopause group as well as the induced menopause patients.

DR CARLOS A P LAMAR, Miami, Fla My experience with diethylstilbestrol for nearly three years agrees closely with that described here today. It should be stressed that, for the treatment of the climacteric very small doses should be employed. There is no need to increase the dosage to the point of producing endometrial stimulation. In cases of senile vaginitis in which larger doses may have to be tried in an attempt to produce relief and endometrial stimulation and bleeding is produced, I have found that the effect can be neutralized by the concomitant

administration of oral synthetic progesterone substances I do not quite agree with the authors' conclusions regarding the suppression of lactation with diethylstilbestrol. I find that diethylstilbestrol administered to the postpartum woman in doses of 5 mg four times a day for from four to six days suppresses lactation without the need for binders. Regarding the toxicity of diethylstilbestrol by the several routes of administration, I have found several striking facts. Certain patients will have excessive toxicity by mouth while tolerating extremely large doses parenterally.

DR KARL JOHN KARNAKI, Houston, Texas. I want to stress that the most important thing is that by giving 1 mg daily of diethylstilbestrol to the menopausal woman or any woman who still has her uterus you will produce bleeding, therefore I advocate smaller doses. The authors mentioned dysfunctional uterine bleeding. I have had more than 800 patients during the last five years. I give such a patient from 5 to 25 mg of diethylstilbestrol into the anterior wall of the cervix. I have now given more than four thousand injections into the anterior wall of the cervix without any harm whatever. For twenty consecutive nights I give a 5 mg diethylstilbestrol tablet. Two to eight days after the last tablet, she will spot for two or three days, bleed for two or three days and then spot again for two or three days. If she bleeds excessively give one half of a 5 mg diethylstilbestrol tablet every hour until the bleeding is checked. Within fourteen to twenty one days, 87 per cent of the patients had a premenstrual endometrium on subsequent examination. As a result of experience with diethylstilbestrol in the treatment of dysfunctional uterine bleeding I feel that radium or a hysterectomy is seldom indicated. I do not find curettage necessary for therapeutic purposes. In threatened abortions I give five 5 mg (25 mg) diethylstilbestrol tablets every fifteen minutes until the pain and bleeding stop, then two 5 mg tablets every hour for six doses, then one 5 mg tablet every hour for six doses and then 10 mg every night until the eighth month. As to the *modus operandi* of diethylstilbestrol in these conditions one must for the present resort chiefly to conjecture. The dosage determines the effect. Small amounts produce proliferation of the endometrium and large doses inhibit the pituitary oxytocins on the uterine musculature, regulate the endometrial vascular system by keeping the spiral arteries dilated and stimulate natural progesterone production, which helps to complete the changes in the endometrium, which I think is one of the most important functions of the progesterone. They also inhibit the excess production of gonadotropin of the anterior pituitary, cause normal rhythmic contractions of the uterus and aid in the normal metabolism of progesterone and estrogens to estrone and estriol. I believe that diethylstilbestrol will replace corpus luteum for the treatment of threatened and habitual abortions and premature labor.

DR JOHN M. FREIHIT, Waterbury, Conn. Initially I have done a pretty good job with the natural hormones. The effect of the natural hormones on the side effects of the menopause and the various functional disorders is very good. Then along came this very strong, potent synthetic hormone, which was put out without a great deal of preparation and used rather indiscriminately. The effects of the natural hormone were immediately exacerbated by the very strong synthetic hormone, not only by serious side effects as nausea and vomiting and general discomfort, but even by return of bleeding sometimes after the menopause had established itself. I don't believe that even natural hormone should be given in the menopausal state unless the pelvic organs are regressing to the natural senile state. In other words, if one takes a pelvic structure which is hypertrophying and give even the natural hormone, one has a great deal of abnormal symptomatology resulting from it. I think, therefore, that in proper cases the use of natural hormone still should supersede the giving of large doses of synthetic hormone. One should at least start patients on natural hormone when indicated instead of giving large doses of synthetic hormone indiscriminately and use the synthetic hormones in small doses to prolong the effects of the natural hormones after the desired effects have been produced.

THE DIAGNOSIS AND TREATMENT OF PRIMARY INTRATHORACIC TUMORS

FRANK S. DOLLEY, M.D.

LOS ANGELES

AND

CAPTAIN LYMAN A. BREWER, III

MEDICAL CORPS, ARMY OF THE UNITED STATES

Because the incidence of primary intrathoracic tumors is apparently increasing, and because with early recognition the great majority may be cured in competent hands with radical surgery, the diagnosis and management of this great group of tumors is becoming more and more important. The literature on this subject has become voluminous and complex, the individual reports dealing mainly with one particular type of neoplasm. When confronted with the individual case, however, the clinician must consider all the possibilities. Therefore it seems important to condense into one article a review of the practical management of this entire group of tumors. Because of the limitations of space, our case reports, covering over 40 extrapulmonary intrathoracic neoplasms removed surgically, on which this review is based cannot be included. They will be published elsewhere.

PRIMARY TUMORS OF THE LUNG

Adenomas of the bronchi exhibit a growth potential somewhere between a purely benign tumor and one of proved malignancy. There is considerable dispute in the literature just how these tumors should be classified. We are certain that the conservative point of view is to regard them as potentially malignant. When they are entirely endobronchial, which is not common, they may be safely treated by bronchoscopic removal. However one must carefully check every case for local recurrence and extrabronchial extension. We have found the planogram of great help in demonstrating extrabronchial extension, which is an indication for pulmonary resection, either lobectomy or pneumonectomy. Pulmonary suppuration the inevitable result of chronic obstruction caused by presence of tumor in the bronchus may also make lobectomy or pneumonectomy imperative.

Clinically, the most prominent symptoms and signs of adenoma are those of bronchial obstruction. Atelectasis, lung abscess and bronchiectasis are the common findings. Thus it is the secondary changes in the lung fields, produced by bronchial obstruction that are usually seen on the chest roentgenogram rather than the tumor itself. Occasionally hemoptysis may be the presenting symptom and the x-ray examination fail to reveal the cause of the hemorrhage. Bronchoscopy is diagnostic, as the great majority arise in the main bronchi. One must not be content with a single piece of tissue for biopsy, as the cell type varies. Often only a superficial inflammatory tissue is obtained, while the real tumor is present at a level just beneath the site of the biopsy. At bronchoscopy we are accustomed to remove as much tumor as possible with the biopsy forceps. The base is then well cauterized with either the electric cautery or 50 per cent silver nitrate. How-

Because of lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

Read before the Section on Practice of Medicine at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

ever, excessive bleeding may prevent adequate bronchoscopic removal of the tumor and be a further indication for pulmonary resection. If recurrence of the tumor occurs with or without bronchial obstruction, radical pulmonary resection is certainly the procedure of choice. Adenomas of the bronchus may grow slowly and perhaps imperceptibly for years and then as the result of some unknown growth stimulus rather suddenly undergo malignant transformation. Finally, lung suppuration secondary to neoplastic bronchial obstruction is usually the immediate cause of death, whether the tumor is benign or malignant.

For these reasons we believe in most instances that radical pulmonary resection is the safest form of treatment.

2 Malignant Pulmonary Tumors—The great majority of primary bronchial tumors are carcinomatous in character. At some time early in the course of their development, all bronchogenic carcinomas are confined entirely to the involved lung. A total pneumonectomy at that time would result in their complete extirpation. Many such cases well past the five year period are on record. The comparatively low operative mortality among those competent to do this work more than justifies immediate exploration in view of the fact that without extirpation death ensues. Following lung removal, it is astonishing how little the life of one who does not indulge in violent physical exertion is limited.

It is of the greatest importance, therefore, that we constantly keep in mind the early suggestive symptoms of bronchogenic neoplasms. They may be divided into two groups: (1) bronchial irritative symptoms and (2) bronchial obstructive symptoms. In the former the growth, still too small to obstruct a bronchus, irritates a vagal nerve branch, a nonproductive harassing cough results, often accompanied by wheezing, sometimes with an occasional streak of blood, more often not. If such a patient does not respond to the usual cough remedies, he should be told of the possible existence of a tumor and bronchoscopy strongly advised (regardless of the fact that he usually feels perfectly well except for the annoying cough).

Not rarely a patient states that he has had a cigaret cough for years or has had chronic bronchitis but that in recent weeks its character has changed with or without blood streaking. An early bronchogenic neoplasm may well be the cause of this change. X-ray examination of the chest often shows only increased lung markings or an irregular shadow at the hilus. Early diagnosis before metastasis has occurred can be made only with the bronchoscope.

Then there is the group in which the symptoms of bronchial obstruction are evident. The symptoms roughly fall into two classes:

1 There is sudden, acute febrile onset with chills, fever and signs of pneumonic consolidation. The type of pneumonia, however, is an atypical one and convalescence is protracted. A tragically large number of such people are told they have delayed resolution, a term that should be discarded from our nomenclature. Bronchial obstruction from malignant neoplasm is not uncommonly the causative factor. At this stage the growth may be confined entirely to the involved lung. When an atypical pneumonia shows little tendency to clear, without delay bronchoscopy should be done.

2 If pyogenic bacteria are imprisoned distal to a neoplastic bronchial obstruction, a lung abscess or pulmonary suppuration may develop. Bronchoscopy is advisable in all such cases. It is the procedure of choice

in any event since bronchial drainage from the affected area is usually more adequate thereafter.

Seventy-five per cent of these tumors can be visualized through the bronchoscope. The X-rays take up where the bronchoscopy leaves off, as the peripheral types usually cast circumscribed shadows of homogeneous density apparent on the radiolucent lung fields. However, since biopsies cannot be taken, this type is more difficult to diagnose. Needle aspiration is often followed by the development of secondary growths along the needle path and should be reserved for those cases manifestly inoperable. Careful sputum examination may show malignant cells. In many instances it is only by surgical exposure of the lung that the true identity of the growth can be determined. Too often because of this uncertainty, lung removal is postponed until extension to the mediastinum renders lung removal futile. All unexplained pulmonary masses must be considered carcinoma of the lung. If metastasis cannot be proved, exploration is indicated.

PRIMARY TUMORS OF THE MEDIASTINUM

The symptoms relative to these tumors are in a very large measure due to the pressure of the growth on contiguous structures. The degree of interference with the functions of the mediastinal organs varies with the location of the tumor, its size and the presence or absence of actual invasion of these organs. Their interpretation is seldom difficult. Pain may be dull or sharp, local or referred. Cough may be absent or extremely distressing. As a tumor grows, it may eventually occlude a bronchus with resultant symptoms of pulmonary infection from bronchial obstruction. Dyspnea, a common symptom, does not necessarily vary with the size of the tumor. A comparatively small growth may cause considerable difficulty in breathing if it obstructs the trachea or bronchus. Hoarseness, dysphagia and engorgement of veins of the neck may be present. If the neoplasm is a benign one, death is entirely the result of compression on surrounding organs.

When the neoplasm is seen by X-ray examination to lie within the mediastinum, it is desirable to consider the various kinds of tumors that are at some time during their existence amenable to surgical removal: their characteristics, their locations and their usual X-ray appearance. Thus by consideration and selection the correct preoperative diagnosis can frequently be made.

1 Teratoid Tumors (dermoids and teratomas)—Since most dermoid tumors of the mediastinum (even though they contain hair) are made up of cells representative of three germ layers, the term "teratoid" tumor as used by Harrington¹ is more accurate. We discuss them together, as clinically they are very similar. The "dermoids" tend to be more cystic, while the teratomas are more cellular and thus are more prone to malignant change. With few exceptions these teratoid tumors are primarily located in the anterior mediastinum from the level of the manubrium to the diaphragm. They are by far the most common benign mediastinal tumors. While they may be centrally placed and be apparent both to right and left of the mediastinal borders, as a rule they project sharply out into the lung fields with a clearcut, well defined convex border. Often trauma apparently initiates increase in size. It is probable that they are present from birth, yet it is usually during the second and third decade that progressive enlargement occurs and pressure symp-

¹ Harrington, S. C. Surgical Treatment of Intrathoracic Tumors, Arch. Surg. 19: 1679 (Dec. part 2) 1929.

toms develop. It is unusual for these tumors to exert pressure on a bronchus sufficient to produce acute pneumonitis. They may grow to enormous size, almost completely collapsing a lung, but without obstruction to the major bronchi. Calcium is often evident in the walls of the cyst. While teeth may be present, they are not common. Hair almost always is found in the dermoids. If a dermoid ruptures into a bronchus, the presence of hair and thick cloudy fluid containing fatty material establishes the diagnosis. While sarcomatous degeneration not rarely occurs, invasion of the cyst wall is late, so that the enucleation of the tumor usually cures. Even when of huge size, they may be enucleated without great difficulty.

Shortness of breath, pain, cough—any one or all of these symptoms may be present. Of course, as in all other mediastinal tumors, other pressure manifestations may exist. The x-ray examination reveals a clearcut anteriorly located, somewhat spherical shadow, nonpulsile on fluoroscopic examination, projecting usually into the lung fields. Needle aspiration is not advisable. Often the cyst contents are too thick to be sucked through a needle even of large caliber. In addition, it is by no means certain that even the comparatively slight hemorrhage from the trauma of such a procedure may not increase the rapidity of enlargement of a tumor already enlarging. If a small "test" dose of radiation therapy is given over the tumor, in three weeks' time any appreciable radiosensitivity may be noted.

2 Mediastinal Lipomas and Liposarcomas—Mediastinal lipomas are very liable to sarcomatous change. The two types, therefore, are considered together. The symptoms and treatment are identical. The lipomas cause symptoms from pressure, while the liposarcomas are extremely invasive and may metastasize. At operation, even with the most careful painstaking dissection, bits of fatty sarcomatous tissue are likely to be left behind resulting in recurrence.

Not only do these primary mediastinal tumors extend laterally into the lung fields, but finger-like processes often burrow along fascial planes to become palpable on the chest wall. Therefore any soft rather movable, mass discovered either parasternally or paravertebrally beneath the deep fascia is more than likely to be but the superficial extension of a mediastinal lipoma.

There are two roentgenologic features of mediastinal lipomas that are strongly suggestive. Since the consistency of the tumor is scarcely more solid than a fibrin clot, the transmission of the cardiac impulse is so complete that under the fluoroscope these tumors usually appear to pulsate with an undulating, wavelike motion. Indeed, if their location should conform to that of the aorta and if the Wassermann reaction should be positive, the diagnosis of aneurysm would seem to be established. The other suggestive finding is that often in an examination of the x-ray film the peripheral zone of the tumor seems thinner than its central portion.

They may grow to enormous size without giving symptoms. Eventually shortness of breath and pain develop, as well as other symptoms of pressure on neighboring organs. Prompt surgical removal is indicated, since these tumors tend to grow very rapidly when once increase in size is apparent. The danger of sarcomatous change makes their immediate excision the more desirable.

3 Mediastinal Tumors of Neurogenic Origin—This group is a very complex one. The tumor under consideration may be derived from a sympathetic ganglion,

the sheath of a sympathetic nerve, a spinal nerve or an intercostal nerve. The character of the tumor depends on whether it is derived from the myelin sheath, the sheath of Schwann or the connective tissue sheath. Thus a wide variety of neurogenic neoplasms may develop from the same mediastinal region, benign neurofibromas or neurogangliomas, and the malignant neuroblastomas and sympathicoblastomas, neurogenic sarcomas, and so on.

All these tumors arise in the posterior mediastinum, usually lie in the costovertebral gutter and are more often found in the upper portion of the chest than in the lower. The benign neurofibromas and gangliomas project laterally into the lung fields and on x-ray examination present clearly defined borders, convex outward. From locally or along the course of an involved intercostal nerve is commonly present. Occasionally a pneumonitis from obstructive pressure against a neighboring bronchus leads to the detection of the tumor. With complete bed rest permitting the neoplasm to drop away from the compressed bronchus, the pulmonary inflammation usually clears. Surgical extirpation of the tumor should then be strongly advised before more serious pulmonary obstruction develops.

Many such tumors are picked up during a routine chest examination. They have given no symptoms. While they remain asymptomatic for years their removal is desirable if no particular contraindication exists. Certainly at regular intervals they should be checked by x-ray examination. If increase in growth becomes evident they should be removed at once. It should be remembered that neurogangliomas are frequently directly over the vertebral bodies centrally located in the mediastinum and that such a location does not necessarily indicate malignancy and inoperability. Their outline is very definite and clearcut.

In the malignant group neuroblastomas and neurosarcomas, certain signs suggest their character. Erosion of ribs or of vertebral bodies is of grave import, it is seldom present in connection with benign growths. Horner's syndrome and hoarseness usually mean that the growth is malignant in character as do dysphagia and a nonproductive, high pitched, dry, metallic cough. Radium therapy is particularly valuable in this group of cases, both as a diagnostic and as a therapeutic measure. There is little likelihood that they are surgically removable. Yet, if x-ray treatment does not clearly reduce its size and the borders of the growth are comparatively well defined, surgical exploration is indicated. Much too frequently a tumor considered though not proved to be malignant has been found at autopsy to be benign and death was due entirely to pressure on the surrounding organs.

It is important to bear in mind that the benign tumors of neurogenic origin occurring in or near a spinal foramen may extend into the spinal canal, compressing the cord. These so-called "hourglass tumors" are by no means rare. If not of too long standing, their excision can be successfully accomplished following removal of the overlying lamina. It must be remembered too that these neurofibromas may occur as a part of von Recklinghausen's disease. Finally, all these previously benign growths may undergo sarcomatous degeneration and are therefore always potentially malignant.

4 Fibroma and Fibrosarcoma of the Mediastinum—A simple fibroma within the mediastinum producing symptoms leading to its diagnosis is rare. In almost all such growing tumors, sarcomatous change has

already taken place. The symptoms are due to compression or interference in function of the surrounding mediastinal organs. X-ray examination shows a clear-cut or spherical shadow which cannot be distinguished roentgenographically from other circumscribed tumors. Since they may originate from a vertebra or the posterior surface of the sternum, they may be located in the posterior or anterior mediastinum. Extension may occur into a spinal foramen causing cord symptoms. For some time, even with sarcomatous degeneration present, they may remain encapsulated. During this period they can be completely enucleated without particular difficulty. When extension beyond the capsular wall has occurred, invasion into and around the surrounding structures progresses very rapidly.

5 Tumors of the Thymus—The most interesting group of thymic tumors is that associated with myasthenia gravis. In more than half of the patients suffering from this disease pronounced hyperplasia or neoplastic change has been found. With few exceptions the neoplasms are benign in character. Aronson² in 1937, Blalock³ in 1939 and Poer⁴ in 1941 successfully removed thymic tumors associated with myasthenia gravis. All symptoms of the disease disappeared following operation. Aronson's and Blalock's tumors were benign. Poer's showed evidence of carcinomatous change. We attempted to remove a malignant thymoma in an advanced case of myasthenia gravis. However, extensive infiltration into the mediastinal structures, especially the wall of the right innominate vein, prevented complete removal. (The patient died of a postoperative pneumonia.) Recently Blalock has removed the thymus in 6 cases of myasthenia gravis. In all some degree of hyperplasia was found. No report concerning this group has been made. While the dramatic results obtained in these 3 cases are encouraging the exact relationship of thymic neoplasms or thymic hyperplasia to myasthenia gravis is as yet not clear. Roentgenologically it is difficult to distinguish between the benign and malignant thymic tumors in all cases of myasthenia gravis with thymic tumor, exploration should be done.

Except in myasthenia gravis, benign tumors of the thymus are comparatively rare. Simple hyperplasia or persistent thymus is usually amenable to x-ray treatment. Surgical extirpation is seldom indicated nor are malignant tumors of the thymus common. Almost without exception they are inoperable when local symptoms develop.

6 Lymphosarcoma and Hodgkin's Disease—The most common tumors of the mediastinum are those of the lymphoma group. There still exists much confusion concerning the various types of malignant diseases arising in the mediastinal lymph nodes. Several exhaustive reports have appeared in the literature attempting to establish tables in differential diagnosis. Because of great variability in symptoms, laboratory findings and clinical course, uncertainty concerning the actual type of lymphatic involvement is usual. Only the microscopic examination of some accessible involved lymph node or occasionally a punch biopsy positively identifies it.

The usual symptoms of involvement or compression of mediastinal organs are present late in the course

of the disease. Early the symptoms of a mild pulmonary infection predominate with dry cough, continued fever and a leukocyte count to 15,000. We have not found the differential leukocyte count helpful in making the diagnosis. Occasionally mediastinal or lung abscess is suspected and the patients are referred to the surgeon for drainage. The x-ray picture varies from a circumscribed mediastinal mass to irregular densities projecting laterally into the lung fields. Rarely isolated pulmonary masses resembling metastatic malignancy are present. In the lateral films the posterior mediastinal space usually is clouded or obliterated. It is unusual for Hodgkin's disease to remain confined entirely to the mediastinum. After a period of time, frequently the axillary or cervical nodes are involved. Biopsy obtained from one of them solves the diagnostic problem. Multiple shadows confined entirely to the mediastinum are more likely to be sarcomatous in nature.

Surgery has been able as yet to offer nothing in either condition. Fortunately, almost all of these primary lymphatic malignant growths are very radiosensitive. Total disappearance under radiant therapy is by no means rare. However, permanent cure seldom results.

7 Primary Sarcoma of the Mediastinum—Primary sarcomas originating within the mediastinum are rare. The great majority represent malignant degeneration of neoplasms that were at first benign. These have already been described. Early in their development these primary sarcomas may prove removable. They can arise from any of the connective tissue elements of the mediastinum. If their location is lateral they extend out into the lung fields. At first before invasion of surrounding structures has occurred their boundaries are clearcut. They cannot, therefore, be distinguished from benign tumors that have been mentioned. Only their comparative rarity makes their presence unlikely.

The ideal treatment is the removal of the benign mediastinal tumor before it becomes malignant regardless of the paucity of symptoms.

SUPERIOR PARAMEDIASTINAL OR SUPERIOR SULCUS TUMORS

Pancoast⁵ first described this syndrome. It was his opinion that this type of tumor arose from branchial cleft derivatives and was a definite neoplastic entity. As additional data accumulated, however, it was discovered that various tumors in this region could give the signs and symptoms described by Pancoast.

The apex of the lung lies immediately lateral to the first thoracic vertebra, protruding upward through the first rib circle. The first thoracic nerve is in contact with the pleura, and the first and second intercostal nerves are just mesial to its apex. The sympathetic trunk with its ganglions lies just mesial to it. The phrenic and recurrent laryngeal nerves are not far distant. Thus a neoplasm arising in this region may cause manifold symptoms early in its growth.

Early extension involving first thoracic and intercostal nerves and the sympathetic chain occurs. The symptoms, therefore, are predominantly mediastinal rather than pulmonary.

Pain, sometimes becoming extreme, is uniformly present in the shoulder and extending down the upper extremity and often to the base of the head. Eventually paresis of the hand may develop. Horner's syndrome is usually present. Frequently such unfortunates are

treated for "neuralgia" for weeks or months. X-ray examination, however, discloses a roughly triangular shadow continuous with that of the mediastinum, corresponding closely to the so-called azygos lobe area. The following differential diagnosis of abnormal shadows of probable neoplastic origin occurring paramediastinally in this upper thoracic quadrant is of importance both from a diagnostic and from a therapeutic standpoint.

1 *Bronchogenic Carcinoma, Main Bronchus Upper Lobe*—A wide triangular shadow with its apex at the pulmonary hilus and its base above extends outward from the upper mediastinum to fill in completely the circle of the first rib. Such a shadow usually represents an atelectatic upper pulmonary lobe. A bronchogenic neoplasm obstructing the main bronchus is commonly the cause. Shoulder girdle pain and Horner's syndrome usually are absent. Cough with or without production usually but not always, is a symptom of prominence. Bronchoscopy may reveal the neoplasm. Because scarcely more than the orifice of the upper lobe bronchus can be seen, often the growth within the bronchus cannot be visualized even with the use of a 45 degree angle mirror placed in the bronchoscope to look up the branch bronchus. If such symptoms occur in conjunction with such a shadow in a person in the cancer age, neoplastic obstruction must be considered the probable causative factor. We have recently tried implantation of radium in inoperable carcinoma in a manner similar to that to be described for sarcoma. No improvement was noted. Prompt surgical exploration is the procedure of choice. Early in its course, lung removal may prove curative.

2 *Bronchogenic Carcinoma, Branch Bronchus Upper Lobe*—Occasionally a smaller shadow similar to the one described appears in this region with its base just above the hilus. Instead of involving the entire apical region with a homogeneous shadow it usually is comparatively small, with less definite borders. This shadow represents lobular atelectasis resulting from an obstructing carcinoma of a branch bronchus of the upper lobe near the mediastinum. There are no nerve pressure symptoms as a rule and often but little cough. Bronchoscopy does not demonstrate the tumor. The diagnosis is rarely made early enough to permit surgical removal.

3 *Bronchogenic Carcinoma, Peripheral Upper Lobe Along the Mediastinum*—A narrow triangular shadow may arise in the circle of the first rib with its base along the mediastinum. The apex does not extend to the hilus. The borders are indistinct because of fine processes extending out into the upper lobe lung field. This represents a bronchogenic carcinoma arising in the periphery of the upper lobe without producing a cough. The x-ray appearance represents the growth of the tumor itself. Because of few symptoms early in its course, as in the previous type just described, rarely can the diagnosis be made soon enough to allow surgical removal.

4 *Extrapulmonary Upper Mediastinal Tumor*—The fourth type of superior sulcus tumor is of mediastinal origin. There is the clearest spherical shadow in the anterior or posterior mediastinum, projecting laterally into the lung fields in the apical region. Intercostal and even shoulder pain may be present. Indeed, it is usually the patient's chief complaint. The shadow may be small, but it is unlikely that it will be triangular. The lateral bulge and convexity strongly suggest that one is confronted with any one of the mediastinal

tumors previously described. Moreover, the pulmonary symptoms are slight, while Horner's syndrome, and pain extending down the arm, are rare. Posteriorly these tumors are usually neurogenic in origin, anteriorly either dermoids or teratomas. Frequently they can be enucleated without great difficulty. It must be remembered, however, that fibrosarcomas may also occur in this region.

Finally, an extrapulmonary upper mediastinal tumor may be of such soft consistency that the intrapulmonary pressure of the lung immediately lateral to it will mold it to a triangular shape entirely consistent roentgenologically with an atelectatic upper lobe, for example, lipoma, fibromyoma, ganglioneuroma. Recently we exposed and successfully removed a ganglioneuroma following a preoperative diagnosis of probable carcinomatous obstruction of an upper lobe. The tumor was very soft and as it was released from the pressure of the contiguous lung at once assumed a roughly globular shape.

We exposed by a posterior approach another tumor corresponding in configuration and symptoms to those enumerated, that is, severe pain in shoulder and arm, Horner's syndrome. Erosion of the second rib, often noticed in these cases, was evident in the x-ray films. Biopsy at operation showed the growth to be a fibromyxosarcoma. It was invasive in character and not operable. However, radon seeds on hand for that purpose were needled into it. They were so inserted as to provide a range of radiant activity of approximately 15 cm. The postoperative course was a most stormy one because of an almost lethal dose of radium. The wound broke down completely, yet eventually it healed. All symptoms, including pain which had been very severe, disappeared. For nearly two years the patient remained well. Local recurrence then appeared and death followed within a few months. His severe pain, however, did not recur. It is well to bear in mind, therefore, that definite relief may be obtained in this manner and that the possibility exists on occasion that the neoplasm may prove to be benign and removable. All attempts at extirpation of fibrosarcomas at this stage have done more harm than good.

PRIMARY TUMORS OF THE THORACIC CAGE

Primary tumors of the thoracic cage make themselves manifest by pain or the presence of a palpable mass, or both. Pain is the most important symptom. It is the result of involvement or pressure on an intercostal nerve by the tumor and so the pain can be located anywhere in the sensory distribution of this nerve. In the case of the upper three thoracic nerves the pain may be "referred" through the same segment of the cord to the brachial plexus and result in the sensation of pain in the arm. Therefore it is of great diagnostic importance to consider any thoracic, upper abdominal or upper extremity pain without a clearly apparent cause to be due possibly to a remotely located neoplasm in or contiguous to the chest wall. A diagnosis of neuralgia, whether the pain is located in the chest wall, abdomen or upper extremity, should never be made until careful x-ray examination reveals no evidence of thoracic neoplasm. This is a point of great importance too frequently forgotten and overlooked by the physician until tumor growth is so far advanced that the chance of successful surgical care has passed. Artificial pneumothorax helps to distinguish the chest wall neoplasms from mediastinal and intrapulmonary tumors.

1 *Bone and Cartilage Tumors* (Osteoma, Osteochondroma, Osteochondrosarcoma, Chondrosarcoma)—All these neoplasms may well be considered together. All such tumors are potentially malignant and should be extirpated as soon as discovered. Primarily they are benign. Even when sarcomatous change has occurred invasion beyond the capsule is at first relatively slow. Their removal at this stage is not difficult. If invasion of the capsular wall is apparent, however, both the parietal pleura immediately surrounding them and that portion of the bony wall to which they are adherent and from which they originate must be excised together with the intervening soft tissues. Serous or even bloody pleural fluid may be present, although it is unusual. Often these tumors are not discovered under the fluoroscope. They may cast but a thin hazy shadow, and bony structures behind or in front may conceal them. Frequently it is necessary to have both a posteroanterior and an oblique Potter Bucky film in order to reveal their exact location.

Unfortunately even highly malignant tumors of the chest wall cannot be distinguished in their roentgenologic contour from benign ones. Rarefaction of adjoining ribs is highly suggestive evidence of their true character, however. Loss of weight without other apparent cause, and bloody pleural effusion, add to the gravity of the situation. If considerable loss of weight has occurred or if actual metastases are discovered or strongly suspected, the removal of the primary growth is of course contraindicated. Otherwise wide extirpation of the tumor is advisable. X-ray treatment has proved of only temporary benefit.

2 *Fibroma*—A pure fibroma of the chest wall is rare. We have had 1 such case. A tumor roughly ovoid, 15 by 12 inches, closely embraced the ninth, tenth and eleventh ribs anterolaterally. Numerous finger-like, grayish white processes extended into muscle tissues and fascia. It seemed identical in type and in extension characteristics with the so-called desmoid that is occasionally discovered in the rectus sheath and muscle. The probability of recurrence in this type of tumor is considerable, since it is not unlikely that one or more of these long advancing tentacles may be entirely overlooked following an apparently complete and certainly painstaking dissection. Since X-ray treatment has no effect, an attempt to extirpate them surgically should be made. Recurrences, however, are to be expected and, since they represent a local growth, should be removed.

3 *Fibrosarcoma*—These tumors are not uncommon. When pain develops leading to their discovery they have become in the great majority of cases invasive. The prognosis for complete removal is bad, although it should be attempted if no evidence of metastasis exists. X-ray treatment has little influence on their course. They usually metastasize early, therefore, not infrequently even when apparently cleanly removed, a fatal outcome is not averted.

4 *Benign Giant Cell Tumors*—These growths are comparatively rare. Early their complete extirpation is possible. They are prone to sarcomatous degeneration. When definite evidence of growth increase exists, it is probable that metastasis has already occurred. X-ray treatment has proved of very great value in this type of neoplasm.

5 *Osteogenic Sarcoma*—In primary osteogenic sarcoma bone destruction occurs very early. The prognosis is thoroughly bad. X-ray treatment frequently is of

considerable help. Provided the extent of the growth or the presence of metastasis is not present as a valid contraindication, extirpation of the tumor with all of the immediately surrounding structures is the procedure of choice.

Ewing's sarcoma with few exceptions, eventually proves fatal. Uniformly it occurs in persons under 30 years of age. Bone destruction is present. Metastases occur very early. Few survive, even when the primary growth is removed widely and early. Radiant therapy is often of great benefit temporarily.

SUMMARY

Having taken a bird's eye view of this great group of intrathoracic neoplasms, we are now in a position to summarize the practical points concerning each of the main types.

Primary tumors of the lung of clinical importance consist of bronchial adenomas (10 per cent) and bronchogenic carcinomas (90 per cent). The signs and symptoms of the two types are somewhat similar. Those of the adenomas may extend over a period of years while those of the carcinomas are present only for a matter of weeks or months before metastasis occurs. The symptoms are mainly bronchial irritative and bronchial obstructive. The bronchial irritative symptoms are cough, or change in character of a long standing cough with or without expectoration, perhaps blood spitting. The bronchial obstructive symptoms begin with wheezing, followed by an atypical pneumonia with protracted convalescence or lung abscess.

Bronchiectasis, a finding common with chronic bronchial obstruction, is frequently seen in adenoma of the bronchus but rarely in carcinoma. It should be emphasized that pain is a late symptom of carcinoma of the bronchus. The diagnosis can be made in 75 per cent of the cases by bronchoscopy, as this percentage of tumors arises in portions of the bronchus visible with the bronchoscope. A positive biopsy can thus be obtained. The peripheral type of bronchogenic carcinoma, invisible to the bronchoscopist, casts a shadow visible on the radiolucent lung fields which represents tumor or pneumonitis distal to secondary branch bronchial obstruction. Thus the X-rays take up where the bronchoscopist leaves off. Lobectomy or pneumonectomy will be eventually indicated in cases of bronchial adenoma because of recurrence following bronchoscopic removal, hemorrhage, extrabronchial extension or chronic pulmonary suppuration. Pneumonectomy should always be performed unless the tumor is limited to distant periphery of a lobe, when the diagnosis of bronchogenic carcinoma is made, and no metastases can be demonstrated, provided no other contraindication exists.

The death rate from intrapulmonary neoplasms (predominantly bronchogenic carcinoma) will be decreased by surgical removal only with early diagnosis. Immediate and serious attention to the following two factors is therefore imperative. 1 Prompt bronchoscopy in all cases of protracted cough, expectoration and hemoptysis, regardless of an innocent appearing chest roentgenogram and apparent excellent general condition of the patient. 2 Prompt surgical exploration in all cases of solitary enlarging pulmonary shadows not otherwise explained, especially if they are circumscribed. An occasional metastatic tumor will be removed and very rarely an inflammatory lesion. But in the vast majority of cases this early surgical exploration will save the life of many a patient with bronchogenic carcinoma.

Primary tumors of the mediastinum make themselves known by pressure on the mediastinal organs. Thus dyspnea, pain in either the chest or the arm, cough, wheezing, dysphagia, hoarseness or distention of the neck veins may be present. Neuralgia in shoulder or arm is always suggestive. X-ray examination uniformly shows a mass in either the anterior or the posterior mediastinum. Dermoids and teratomas are the most common benign tumors of the anterior mediastinum. They are circumscribed, slow growing, radioresistant tumors usually presenting symptoms in the first and second decades of life. The most common benign tumor of the posterior mediastinum is neurogenic in origin. Pain is the most prominent early symptom, while the symptoms of mediastinal obstruction come on late. On x-ray examination a round circumscribed shadow is seen in the posterior mediastinum.

The lymphosarcomas are the most common malignant mediastinal tumors. They present rapidly enlarging irregular x-ray shadows extending from either the posterior or the anterior mediastinum. Their extreme radiosensitivity distinguishes them from the benign tumors, which are radioresistant. Since lymphosarcomas are inoperable as soon as they produce symptoms, a "test dose" of x-ray therapy should be tried preoperatively in all cases of mediastinum tumor where a lymphoblastoma is a possibility. All benign mediastinal tumors should be removed surgically as soon as they are diagnosed unless a definite contraindication exists, since they may eventually prove fatal from mediastinal obstruction due to their size or because of malignant degeneration. The operative mortality in experienced hands is very low. Other less common mediastinal tumors, because of their diverse characteristics, cannot be summarized here.

Superior sulcus tumors represent a variety of new growths arising in the superior paramediastinal region. Pain in the shoulder and arm, Horner's syndrome and a dry cough are the prominent symptoms. The x-ray picture is that of a triangular shadow arising from the upper superior mediastinum. Primary bronchogenic carcinomas producing either lobar or lobular atelectasis of the upper lobe of the lung account for two of the main types of shadows seen on the x-ray film. A peripheral bronchogenic carcinoma arising near the mediastinum and not causing atelectasis produces an irregular paramediastinal shadow. Any of the mediastinal tumors that have been discussed may account for the fourth main type of superior sulcus tumor. Bronchoscopy rarely aids in making a positive diagnosis of tumors in this region. After a "test dose" of x-ray therapy, surgical exploration is indicated. With the exception of the benign mediastinal tumors in this location, the results of surgery have been discouraging, as in most instances the tumors are inoperable when diagnosed.

Primary tumors of the thoracic cage are characterized by pain and often the presence of a palpable mass. The pain may be in the arm, chest or abdomen. Benign tumors of the bony cage, the chondromas and osteomas, are potentially malignant and should be removed as soon as diagnosed. They present circumscribed shadows on the ribs or cartilage without evidence of bony destruction. The malignant group (osteosarcoma and the like) usually show evidence of bony destruction if extracapsular extension has occurred. Early in their course they may have been benign and at that time were operable. The results of roentgen therapy and

radical surgery have been most disappointing in cases of malignant tumor of the bony cage. Therefore, as soon as a benign chest wall tumor is diagnosed it should be removed surgically, provided no valid contraindication exists.

CONCLUSIONS

- 1 The presence of an intrathoracic neoplasm can be usually detected by x-ray examination and bronchoscopy, the bronchoscopy taking up where the x-rays leave off. (When an intrathoracic tumor is suspected, the examination is flagrantly incomplete without the use of these diagnostic procedures.)

- 2 All persistent or enlarging, solitary chest wall, mediastinal or pulmonary roentgen shadows should be suspected of being neoplastic until proved otherwise.

- 3 All patients with the symptoms of persistent bronchial irritation or obstruction should early have the benefit of bronchoscopy. A negative bronchoscopic examination does not exclude its presence in an upper lobe or in the other lobes beyond where it can be visualized through the bronchoscope.

- 4 The vast majority of benign intrathoracic tumors are liable to malignant change.

- 5 Practically all enlarging centrally placed intrathoracic neoplasms, unless they are removed, cause death from pressure if they are benign, or from extension if they are malignant.

- 6 With the exception of the lymphoblastoma group, roentgen therapy is palliative and not curative. Often such therapy is needlessly prolonged until a once operable case becomes inoperable.

- 7 At some time during their growth most intrathoracic tumors can be removed.

- 8 The operative mortality is surprisingly low and is being steadily reduced as experience and improvement in surgical technique increases.

- 9 If the diagnosis of an intrathoracic neoplasm has been made by x-ray examination or bronchoscopy and lymphosarcoma and metastases are ruled out surgical exploration is at once indicated. Only a bona fide contraindication, such as cardiac decompensation, and not the apparent good general health of the patient or the reluctance of the doctor to take the responsibility, should prevent operation.

427 South Arden Boulevard

ABSTRACT OF DISCUSSION

DR. ROY W. SCOTT, Cleveland: Lobectomy and pneumonectomy, impressive accomplishments of thoracic surgery in the past few years, have doubtless prolonged the lives of patients with lung cancer but in interpreting results we can speak only of survival periods and not cures. Although the primary growth and local metastasis may be removed, we have no assurance that the patient is cured, since at any time up to several years bone or other metastasis may occur just as in patients with cancer elsewhere. Squamous cell cancers of the lung rarely metastasize widely and therefore offer the best prognosis from operative removal.

CAPTAIN LYMAN A. BREWER III, M. C., A. U. S.: The chairman's remarks are true that the cures in pulmonary cancer have been few as compared to the reported deaths. The reasons are (1) failure of early diagnosis and (2) lack of appreciation that early radical surgery is curative. This is an era when tumors are treated by surgery and x-rays. With the exception of intrathoracic lymphosarcoma, roentgen therapy has been singularly ineffectual. Most benign chest tumors are potentially malignant and often cause death from pressure on mediastinal structures. Therefore, until the future brings a simpler method, we must recognize that radical surgery offers the only chance of permanent cure for intrathoracic tumors.

ANEURYSM OF THE RENAL ARTERY

REPORT OF A CASE

OSWALD S LOWSLEY, M D

AND

EDWARD M CANNON, M D

NEW YORK

Aneurysm of the renal artery is a rare clinical and pathologic entity. Medical literature contains reports of only 74 cases. The first account of a case of "renal" aneurysm was published by Dr. Daniel Nebel¹ in 1719. For two and a quarter centuries this well known case of Nebel's has been incorrectly translated and misquoted. The patient was not a physician and did not have a renal aneurysm but suffered from an aortic aneurysm. Many of the earlier papers reveal incomplete case reports and do not warrant a clinical or pathologic diagnosis of renal aneurysm. Keen² in 1900 and Morris³ also in 1900, were the first to write more extensively on the subject. Summarizing articles were published by Vogeler⁴ in 1922, Conroy⁵ in 1923 and Gerard⁶ in 1930. Mathe⁷ in 1932 wrote an excellent review of the subject and tabulated 55 cases from the literature.

It is our purpose to bring the literature up to date, report our own case (diagnosed preoperatively) and briefly review the subject. The accompanying table contains a summary of 20 cases reported in the literature since Mathe's exhaustive review, these, with the 1 presented here, bring the total number of cases to date to 75.

REPORT OF CASE

A R, a white woman aged 47, first seen in the outpatient department (urology) of the New York Hospital on Sept. 20, 1941, complained of pain in the right flank and discomfort in the right upper quadrant. She stated that her kidney trouble had begun six years before at which time she had pus in the urine and chills and fever. The pyuria and other symptoms subsided in a few weeks and she had no further trouble until July 1941 when she had dull pain in both flanks accompanied by chills and fever. The persistent gnawing pain in the right flank continued until the time of admission.

Physical examination revealed no abdominal masses. Slight tenderness was elicited in the right costovertebral angle and flank. The blood pressure was 116 systolic and 72 diastolic.

Cystoscopy and retrograde pyelography were done in the clinic. The flat plate showed both renal shadows to be normal in size, shape and position. Lying medially and outside of the right kidney was a ringlike shadow with a denser periphery and rarefaction of the center (fig. 1). The pyelogram revealed no abnormalities of the kidney proper. The area of increased density, which measured 15 cm in diameter, was seen to be above the right ureteropelvic junction (fig. 2). A diagnosis of calcified aneurysm of the right renal artery was made by Dr. William E. Forsythe, Jr.

The seriousness of a renal aneurysm was explained to the patient, and on October 14 she was admitted to the department of urology, James Buchanan Brady Foundation, of the New York Hospital for further study and subsequent operation.

Excretory urograms, made on the second hospital day, revealed a normally functioning upper urinary tract. The previously noted ring shaped shadow remained in the hilar region of the right kidney.

On October 20 (the sixth hospital day) under spinal anesthesia the right kidney and renal pedicle were exposed by the usual lumbar approach. Examination and palpation of the renal pedicle disclosed a faintly pulsating small swelling in the region of the hilus of the kidney. The lesion being definitely an aneurysm, nephrectomy was performed (fig. 3).

The patient had an uneventful recovery and was discharged on the fifteenth postoperative day. Since the nephrectomy she has been entirely relieved of the preoperative dull flank pain.

Fig. 1—In this flat plate medial to the right kidney shadow is a wreathlike area of increased density disrupted in one portion. This represents an aneurysm of the renal artery.

Pathologic examination of the removed kidney by one of us (E. M. C.) showed the following:

Gross. On the posterior aspect, at the bifurcation of the renal artery, was a small saccular aneurysm (fig. 4). The aneurysmal sac was yellow-red, fairly smooth in contour and firm and measured 14 by 11 by 0.9 cm. Bisection of the sac showed the aneurysmal opening to be 0.4 cm in diameter. The orifice of the aneurysm was located on the posterior wall at the point at which the artery leaves the bifurcation to proceed to the upper pole. The wall of the sac contained calcific atheromatous plaques. A longitudinal section of the kidney showed a normal renal configuration. A few discrete, pale areas were observed in the cortex. The medullary pyramids were grossly normal in appearance, and there was no flattening of the apices. The major calices and the pelvis were not dilated. The mucosa was smooth, and there was no evidence of tumor ulceration or calculus.

Microscopic. Microscopic examination of the wall of the aneurysm revealed hyalinized collagenous tissue. Deposits of amorphous calcium salts were noted throughout the wall. Weigert stain showed absence of elastic tissue (fig. 5).

The pathologic diagnosis was true aneurysm of the right renal artery.

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital.

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Urology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1942.

Summary of Twenty Cases of Aneurysm of

Year	Author	Sex	Age Years	Classification and Location	History	Symptoms	Physical Findings
1902	Nathu	♂	47	True aneurysm superior main branch of left renal artery	In 1920 fell in bathtub striking left lumbar region immediately passed red blood in urine repeated attacks of left renal colic	Severe attack of left renal colic	Tenderness on deep palpation in upper left quadrant and left costo vertebral angle
1904	Brinkman J Iowa M Soc 24 54 1934	♀	27		Sudden stablike pain in upper quadrant	Vomiting pain in left upper quadrant subsided after 6 days after discharge following exploratory operation pain recurred occasional red blood cell in urine	Evidence of free fluid in peritoneal cavity moderate rigidity in left renal region and left upper quadrant urine normal
1906	Wesson and Fulner 13	♂	78	True aneurysm left renal artery	Prostatectomy 2 months before for carcinoma generalized arteriosclerosis no trauma	Severe weakness pain in sacrum frequency nocturia	Cystoscopy purulent urine from both kidneys
1906	Loughnane Brit J Urol 8 146 1936	♂	50	Aneurysm left renal artery and abdominal aorta	Colicky pains in left loin for 2 years syphilis malarial	Pains in left flank frequency nocturia	Soft mass in epigastrium hard palpating mass in left loin
1907	Flück Zentrbl f Chir 64 170 1907	♀	40	True aneurysm at bifurcation of left renal artery	Pulmonary tuberculosis (cured) no trauma	Asthenia myalgia hiccups symptoms of thyroid intoxication	Cachectic hypertension—systolic 100 mm Hg. no other abnormal findings
1931	Kapel Chirur 9 801 1937	♀	57	Calcified true aneurysm branch of left renal artery	Left abdominal distention and left renal colic	Pain in left hypochondrium and flank	Negative
1937	Mekay 18	♀	54	True aneurysm left renal artery	Run over by a wagon intermittent pain and discomfort in left kidney region Wasermann negative	Pain in left side hematuria	Pain tenderness spasticity on pressure over left kidney cysto copoly bloody reflux from left ureter no excretion of indigo carmine from left kidney
1938	Ostling 14	♀	24	Ruptured aneurysm branch left renal artery	Pregnant	Sudden pain in left abdomen vomiting symptoms of shock and collapse	Fundus of uterus 3 finger below xiphoid palpable swelling in left flank
1938	Kustner Ztschr f Urol 442 1938	♀	80	Intrarenal aneurysm right	Episode of hematuria 6 months previous no trauma	Suprapubic distress severe hemorrhage from bladder	Hard movable tumor in right lower quadrant and flank cysto copoly bleeding from right ureteral orifice
1938	Smith and Walkling Bull. Ayr Clin Lab Pennsylvania Hosp 3 203 1938	♀	50	True aneurysm superior polar accessory renal artery	Cholecystectomy 1921 low back pain right upper quadrant pain	Pain in right upper quadrant	Acute tenderness in right flank and moderate tenderness in right upper quadrant
1938	Solis Cohen and Steinbach Radiology 31 10 1938	♀	56	True aneurysm in inferior branch right renal artery	Progressive weakness weight loss worse support for posterior right kidney no trauma pain or hematuria	Nocturia weakness	Posterior right kidney with expansible mass the size of a lemon near the lower pole transmitting a definite bruit and thrill
1939	McClelland Tr Am A Genito Urin Surgeons 12 109 1939	♂	61	True aneurysm intracapsular branch right renal artery	No trauma	Hematuria 1 day only	Murmur heard in upper left abdomen immediately under costal margin in a systolic bruit with radiation to back
1939	Onell and Valencic 15	♀	40	Ruptured true aneurysm left renal artery	Suspicion of congenital syphilis repeated pregnancies glomerular nephritis 6 months pregnant no trauma Acute hemorrhagic nephritis at 2 years symptoms of typical Goldblatt syndrome	Intestinal pain sudden loss of consciousness signs of internal hemorrhage	One hour after onset large hard mass palpable in right lower and extended low from costal arch to iliac fossa
1940	Howard Forbes and Lipcomb J Urol 44 808 1940	♀	5	Multifocal true aneurysm left renal artery	Acute hemorrhagic nephritis at 2 years symptoms of typical Goldblatt syndrome	Restless headache	
1941	Howard Suby and Harberson 9	♀	54	False aneurysm branch of right renal artery	Pulmonary tuberculosis heavy fecula in right abdomen nocturia no trauma or renal tumor	Nausea and vomiting severe pain in bowels shock	Large mass palpable in right upper quadrant extending an inch below umbilicus and to midline later to left pelvis and down to pelvis
1941	Howard Suby and Harberson 9	♀	50	True aneurysm right renal artery	Bilateral salpingo oophorectomy and appendectomy 11	Persistent severe tenderness in right lower abdomen	Tenderness in right lower abdomen urine normal
	Harberson 9			True calcified aneurysm branch of left renal artery	Two year history of difficulty in voiding frequent nocturia 45 x	Inability to void	Tender palpable mass in suprapubic region prostate hard and enlarged 2 x blood pressure 160/100
1941	Smith 9	♂	41	Aneurysm right renal artery	In 1916 wounded in right loin by shrapnel since then had nothing pain in right loin	Acute discomfort in right loin hematuria	Slight tenderness of costo vertebral angle bruit and pulsation over right loin cysto copoly blood from right ureteral orifice
1942	Child (to be reported)	♀	33	True aneurysm main branch right renal artery	Nine year history of intermittent pain in right upper quadrant	Pain in right upper quadrant 3 days	Blood pressure 160/100 ill defined tender mass (6 by 5 cm) in right upper quadrant
1942	Lowsley and Cannon	♀	47	True aneurysm right renal artery	Intermittent pain in right flank chills and fever pyuria 6 years	Persistent gnawing pain in right flank slight frequency and nocturia 2 months	Slight tenderness in right costo vertebral angle and flank urine 90 white blood cells 2 plus clumping culture Escherichia coli (bladder)

the Renal Artery Reported from 1932 to 1942

Roentgen Findings	Diagnosis (Preoperative)	Treatment	Result	Pathologic Condition
Enlarged irregular left kidney 7 cm cyst in upper pole ring shaped shadow with a less opaque center outside the pelvis in the parenchyma near the hilus encroaching on the infundibulum of a dilated upper primary calyx	Renal calculus cal cified renal cyst	Nephrectomy	Cured	Dilated upper calyx with narrow in fundibulum containing "hard calculi" aneurysm superior branch of left renal artery sac 15 mm in diameter calcification of aneurysmal wall atheromatous changes in renal artery
None	Renal aneurysm	Exploratory operation bloody fluid in perito neal cavity concluded hemorrhage from retro peritoneal source nephrectomy	Cured	Kidney buried in huge clot
Flat plate shadow 15 cm in diameter with a dense periphery and a clearer center medial to catheter and over left 12th rib pyelogram shadow to medial side of left kidney at level of superior calices	Renal aneurysm	Supportive	Death postop toxic anuria	Renal artery soft except for 1 cm dilatation
Considerable displacement of left kid ney and ureter	Undetermined aneurysm of renal artery suspected	Laparotomy revealing both renal and abdom inal aneurysm	Death in 2 months	No autopsy
Pyelogram (1932) left renal tumor In 1936 check up revealed tumor to have enlarged	Renal tumor	Nephrectomy	Improved blood pressure fell to 130	Hypernephroma of left kidney true aneurysm left renal artery at bifur cation complete lining of intima
Circular shadow within upper kidney pole just inside renal pelvis	Calcified tuber culous focus	Nephrectomy	Cured	Nut size calcified aneurysm
Flat plate ringlike shadow dense periphery and central rarefaction right pyelogram extrarenal shadow	Undetermined	On delivering left kidney into wound hemorrhage due to rupture of aneu rysm occurred hemor rhage controlled nephrectomy	Death 4 days post operatively from pneumonia and myocardial failure	Saccular aneurysm 10 by 12 mm just proximal to bifurcation of left renal artery wide separation of inner and outer wall evidently dissecting aneurysm involving sac
None	No diagnosis	Supportive	Death a few hours after onset	Large left retroperitoneal hemor rhea
Catheter deviated toward midline low kidney right no visualization of pelvis and calices	No diagnosis	Nephrectomy	Cured	Old intrarenal aneurysm with perfora tion into renal pelvis aneurysm size of small apple wall impregnated with calcification arteriosclerosis of vessels
Ring calculus posterior and outside right kidney	Calculus in cystic duct	Nephrectomy	Cured of flank pain	Saccular aneurysm 0.7 mm in diam eter of accessory vessel thickening of intima with calcific deposits
Extrarenal dilated pelvis upper calyx dilated entire midsection of kidney distorted by large cystlike area with thin partly calcified wall	Aneurysm renal artery	Nephrectomy	Cured	Large saccular aneurysm inferior branch of renal artery 7 cm in diameter wall thin and partially calcified
Circle of calcification size of 10 cent piece over right kidney and last rib ring of calcification separate from calices but in kidney substance		Nephrectomy	Cured	1 by 5 cm cyst in upper pole beneath capsule at lower pole a fluctuant area of blood two large dilated vessels with thickening of walls within pel vis
None	No diagnosis	Pulsating mass in renal fossa hemorrhaged at operation	Death 6 hours postoperative	Hazelnut sized aneurysm of left renal artery right kidney atrophied microscopically left kidney showed nephrotic stage of chronic glomeru lar nephritis
Pyelograms negative		Craniotomy small area of necrosis in right frontal lobe right sym patectomy	Cured blood pressure 3 months postoperative 120/90	Thin saccular multiloar aneurysm of left renal artery microscopically chronic glomerular nephritis
Large tumor in mass in right kidney area with calcification in capsule	Calcification of solitary cyst	Emergency nephrectomy renal fascia opened with hemorrhage	Death day of operation	Aneurysmal sac adjacent to kidney measuring 2 1/2 by 9.5 cm covered with capsule of kidney calcification of wall
Pyelogram slight angulation of right ureteropelvic junction	Interabdominal lesion	Laparotomy revealed a round soft collapsible pulsating mass	Cured	Thimble shaped pink gray yellow aneu rysmal sac true aneurysm and atherosclerosis of right renal artery
No roentgen findings	Acute urinary retention carci noma of pros tate pyelone phritis hyperten sion cardiac decompensation	Supportive	Death	Carcinoma of prostate with local extension pyelonephritis contraction and calcification of right kidney diverticulum of bladder hemorrhagic cystitis calcified aneurysm 1 cm of n branch of left renal artery
Loss of definition pelvis distorted and irregular	Aneurysm of renal artery	Nephrectomy clamp left on pedicle for 3 days	Cured	Aneurysm of right renal artery
Lateral and below right transverse process of first lumbar vertebra a ringlike shadow with increased peripheral density pyelograms nor mal gallbladder series negative	Chronic chole cystitis and cholelithiasis with hydrops	Exploratory laparotomy for a probable chronic cholecystitis discovered a calcified pulsating small renal aneurysm subsequent nephrectomy	Cured	True aneurysm (1 cm in diameter) located at bifurcation of right renal artery section through aneurysmal wall revealed hyalinized fibrous tissue no elastic tissue remained heavy deposits of lime salts
Plain x-ray lying medially and out side right kidney a ringlike shadow with a dense periphery disrupted in one portion and rarefac tion in the center pyelogram increased density seen to be above the ureteropelvic junction	Aneurysm of the right renal artery	Nephrectomy	Cured	True aneurysm 1 1/2 by 1 1/2 by 0.9 cm on posterior aspect at the bifurca tion of the right renal artery wall of sac contained calcific atheromatous plaques microscopic examination of the wall of the aneurysm revealed hyalinized collagenous tissue de posits of amorphous calcium salt absence of elastic tissue

ETIOLOGY

Most writers on aneurysm of the renal artery state that, statistically, trauma—either to the loin back or upper part of the abdomen—is the most important causative factor. In the last century, the introduction of the germ theory, and increased knowledge of the diseases of the arterial wall itself and of congenital defects of the arteries have produced new concepts of the etiology of aneurysms. It is doubtful whether trauma per se causes aneurysm. However, trauma may be the impetus for an aneurysmal dilatation in a renal artery which is already friable or otherwise weakened by congenital defect, infection or other disease. Gerard stated that 28 per cent of the cases reviewed by him were late sequelae of trauma to the kidney area. According to Mathe, 50 per cent of the 55 cases collected by him

defects of the media of the cerebral arteries at the apexes of the angles formed by arterial branching bifurcation. Undoubtedly, arterial wall defects occur at the bifurcation of the renal artery and play an important part in the production of renal aneurysms.

It is well known that arteriosclerosis and syphilis are important factors in the formation of aneurysms. However, these diseases have played a relatively minor role in aneurysm of the renal artery, only 4 patients in the reported series having had syphilis and 12 arteriosclerosis. Periarteritis nodosa although occasionally generalized, displays a particular affinity for the renal artery, and a small number of cases have shown this pathologic entity at autopsy.

INCIDENCE

Judging from the number of reported cases, aneurysm of the renal artery is very rare. It might be questioned whether this rarity is actual or due to failure to recognize the lesion because of the obscurity or complete lack of signs and symptoms, were it not that autopsy records bear witness to the infrequency of its occurrence. Howard, Suby and Harberson⁹ found only 10 renal aneurysms in a series of 69,819 autopsies.

Age apparently has little bearing on the incidence of this lesion. The youngest patient was 9 months and the oldest 82 years. Although 32 patients were in the fifth and sixth decades of life, it is difficult to prove that renal aneurysm of spontaneous origin is more likely to develop in this age group, since it may exist for years without producing symptoms.

Of the 72 patients whose sex was stated, 40 were males and 32 females.

PATHOLOGY

Two fundamental factors underlie the development of an aneurysm: (1) the vascular wall is weakened by congenital defect, disease or trauma, and (2) the pathogenesis is directly related to intrinsic and extrinsic vascular pressure.

Renal aneurysms are classified as "true" and "false." A true aneurysm is any pathologic localized dilatation of the artery that retains one or more of the coats of the arterial wall. Wesson¹⁰ states that the term "false aneurysm" is a misleading one and that the diagnosis should be "traumatic spontaneous rupture of the renal artery with anatomic control of hemorrhage."

A true aneurysm is the result of a congenital defect, a vascular disease, a degenerative process or inflammatory changes of the arterial coats. Its sac is a saccular or fusiform dilatation of the wall itself. True aneurysms are usually small, ranging from the size of a pea to that of an orange. They often show calcareous deposits which are opaque to the roentgen ray. In the arteriosclerotic type of aneurysm, the beginning lesion is a subintimal plaque which progresses to implicate the vascular wall. A true arteriosclerotic aneurysm seldom perforates but, owing to its long existence and weakening of the sac, it may rupture spontaneously or perforate, from insignificant trauma, to form a false aneurysm. So long as a true saccular aneurysm remains unruptured it is not likely to produce any distinct pathologic changes. Pressure and occlusion of the aneurysm may cause thrombi and infarcts of the renal parenchyma. If the aneurysm is condensed within the capsule it may cause some pressure necrosis.

Fig. 2—Pyeloureterogram showing above the right ureteropelvic junction a wreathlike shadow with a denser periphery and rarefaction of the center. The shadow is characteristic of a renal aneurysm.

presented a history of trauma. Bringing the literature up to date reduces this incidence to 33 per cent.

Intracranial saccular aneurysms occurring in the angles formed by bifurcation or branching arteries have been variously termed "congenital," "developmental," "bifurcation" and "berry" aneurysms. The exhaustive studies of Richardson and Hyland⁸ have shown that "berry" and basal cerebral aneurysms are congenital and are caused by defects in elastic tissue and local

False aneurysms of the renal artery are usually larger than true aneurysms. The smallest one in the published cases measured 10 by 15 cm., and Morris reported a false aneurysm which filled one half of the patient's abdomen. The wall of a false aneurysm is composed of condensed fibrous tissue developed around the extravasated and coagulated laminated blood. To this mass the surrounding structures become more or less firmly matted.

Whether a false aneurysm is formed as the result of trauma or disease, indirectly by the rupture of a saccular aneurysm or directly by the rupture of the artery, the resultant extrinsic pressure changes, displacement of organs and renal damage are the same. A false aneurysm may rupture into the peritoneal cavity, causing extensive hemorrhage. It may extend into the retroperitoneal space, rupture and form a large hematoma. Death by exsanguination may result if a false aneurysm ruptures into the renal pelvis. Blood may distend the pelvis and calices and produce complete absorption of the renal parenchyma. Partial or complete atrophy of the kidney may result from extravasated blood within the capsule. The hematoma may be entirely outside the renal capsule, and the kidney—if any of it remains—will be spread out in the wall of the sac. Blood may course along the vessels and thus gain entrance into the capsule of the kidney and then rupture into the calices.

SIGNS AND SYMPTOMS

True aneurysms present no definite syndrome of symptoms. The most constant complaint is pain referred to the upper part of the abdomen or to the lumbar region. Hematuria and the presence of a mass are infrequently observed in this type of aneurysm.

The cardinal signs and symptoms of a false aneurysm or of a ruptured aneurysm are pain, tumefaction and hematuria. Tumor masses that are progressing in size and aneurysms that have perforated give rise to pain. With slowly growing aneurysmal sacs, the pain appears only when the sac has reached a considerable size. Pain variously described as progressive, throbbing or colicky, was present in more than 50 per cent of the reported cases.

As a true aneurysm increases in size and ruptures spontaneously or traumatically to form a false aneurysm or retroperitoneal hematoma, a tumor mass becomes palpable in the flank or upper part of the abdomen. This tumefaction may develop quickly or may be progressive over a period of months. Tumors ranging from the size of an orange to one that nearly filled the abdomen have been reported. As a rule, the mass is smooth, firm, more or less tender and fixed in position and does not move with respiration. A systolic bruit or pulsation, when present, is pathognomonic. This finding was elicited (or mentioned) in only 7 of the reported cases. The absence of a bruit or pulsation is explained by the fact that a blood clot intervenes between the inner, pulsative part of the tumor and its capsule, diminishing the impulse of the systolic waves.

Hematuria is a characteristic symptom of ruptured aneurysm when the bleeding follows trauma and pre-

cedes pain and tumefaction. It occurs when the aneurysmal sac has perforated a calyx or has established a direct communication with the renal pelvis. Hematuria in cases of true aneurysm is the result of renal thrombi and subsequent infarction. The bleeding may be insignificant but usually the hematuria is more severe than that induced by stone or neoplasm. The hemorrhage may be so extensive as to result in exsanguination, and death has occurred in 14 cases.

DIAGNOSIS

The clinical diagnosis of renal aneurysm is difficult, and in only 12 of the 75 reported cases was the condition correctly diagnosed before operation or autopsy.

Small true aneurysms rarely present symptoms and are usually discovered accidentally during investigation

Fig. 3.—The right kidney has been exposed showing aneurysm of the renal artery.

of the kidney, or they are found at autopsy. The usual calcific deposits in the wall of the aneurysmal sac, being opaque to roentgen rays, appear as a ringlike or wreathlike shadow on the film. This shadow is suggestive of a calcified renal aneurysm, but it must be differentiated from gallstone, renal calculus, calcified lymph gland, calcification in neoplasm, calcified cyst and calcification of autonephrectomy. Opinions differ as to the diagnostic value of this finding. Soderlund¹¹ and Renck¹² consider a ringlike shadow, with a dense periphery, in the region of the renal pelvis as characteristic of renal aneurysm. Wesson and Fulmer¹³ state that a calcified cortex interrupted in one portion is pathognomonic. Mathe questions the value of the sign

and states that the shadow cannot be differentiated from those cast by other shadow-casting lesions. A review of the literature reveals that this ringlike shadow has been reported as being present in 12 cases. In our own case, and in the cases of Soderlund and Wesson and Fulmer, the diagnosis was made on this roentgenographic finding.

The ringlike shadow cast by a renal aneurysm has been incorrectly interpreted as a calcified tuberculous focus, a neoplasm with calcification, a calcified cyst, a calcified lymph gland and a gallstone.

False aneurysms offer a particularly perplexing problem in diagnosis, for they frequently present a clinical picture similar to that of rupture of the kidney. Traumatic rupture of a false aneurysm or spontaneous perforation of a true aneurysm is to be considered in the presence of intermittent hematuria associated with excruciating pain in the loin and a rapidly or slowly enlarging immobile tender swelling in the flank. How-

ever, five years elapsed in Keen's and Morris's cases. The usual cause of death of patients who are not operated on is exsanguination from hemorrhage of a ruptured aneurysm into the renal pelvis, retroperitoneal tissues or peritoneal cavity. Of 37 patients who underwent operation 8 died—a mortality of 21 per cent.

TREATMENT

Prociastination in the presence of symptoms of false or ruptured aneurysm may result in the early death of the patient. Any evidence presenting itself of an enlarging perirenal hematoma, whether it is due to rupture of an aneurysmal sac, to trauma to the kidney or to any other renal pathologic condition, demands immediate surgical investigation.

The operative approach is the usual classic flank incision. If a pulsating aneurysmal sac or a perirenal hematoma is encountered, the mass should be exposed and handled very carefully, for the slightest tear in the sac may result in brisk hemorrhage. Shock and death may occur, as in the cases of Onell and Valencia.¹⁵ As soon as the presence of an aneurysm is determined, the renal pedicle should be exposed, clamped and tied, or, if the tumor is large and hemorrhage appears inevitable, the friable pedicle should be approached transperitoneally and clamped near its branching from the aorta.

Of 37 patients operated on, 8 died. Morris's patient died after an attempt was made to extirpate the sac. Two operative deaths occurred during incision and drainage of the sac (Barnard in 1900,¹⁶ Chisholm in 1926.¹⁷) One postoperative death was the result of hemorrhage from the tearing of the aneurysmal sac (Onell and Valencia). McKay¹⁸ encountered hemorrhage at operation, but the bleeding was controlled, the pedicle being clamped, cut and ligated. The patient left the operating room in good condition only to die four days later from pneumonia and myocardial failure.

Of the 29 patients treated by nephrectomy, 26 survived. Skillern¹⁹ left pedicle clamps on because of the close relation of the aneurysm and aorta. Smith²⁰ encountered hemorrhage and left the pedicle clamps on for three days. Hemorrhage did not follow the removal of the clamps in either case. Orth²¹ was able to evaluate the clots and successfully suture the tear in the wall of the aneurysm, and a year later he reported that the kidney was functioning satisfactorily. Callahan and Schultz²² extirpated a saccular aneurysm and preserved the artery.

Fig. 4—A sectional view of right kidney showing renal vein and renal artery with aneurysm. B posterior surface of the kidney showing the aneurysm opened and the communication between the aneurysm and the renal artery as indicated by the probe.

ever, this syndrome may also be presented by a ruptured kidney, so that clinical differentiation is practically impossible, and only an exploratory operation can settle the question.

In unruptured false aneurysm, the tumor mass is the most valuable sign, with the exception of a pulsating tumor, which is pathognomonic but has been noted in only 7 cases.

PROGNOSIS

The prognosis of symptom producing aneurysms of the renal artery is grave. In the reported cases death occurred in all in which operation was not performed. The fatal outcome may be rapid, as occurred with Ostling's¹⁴ patient, who died a few hours after the onset of symptoms.

Most of the patients have died within a year of the appearance of symptoms, but some persons harboring renal aneurysms have lived for considerable periods of time before death occurred or operation was per-

When a unilateral true aneurysm is suspected or diagnosed roentgenographically—even though signs and symptoms are lacking—an exploratory operation should be done and, if the impression is confirmed, nephrectomy performed. Radical surgery is indicated because a small true aneurysm the wall of which is weakened and friable may rupture in the near or remote future. A calcified aneurysm may never enlarge or perforate, but nephrectomy removes the possibility.

SUMMARY AND CONCLUSIONS

1 Aneurysm of the renal artery is a rare clinical and pathologic entity. Only 75 cases have been reported to date, including a case of true aneurysm diagnosed preoperatively and presented here.

2 A congenital defect in the wall of the renal artery, particularly at its bifurcation, is a hypothetical factor in the etiology of aneurysm. It is questionable whether trauma per se produces renal aneurysm.

3 Only 12 of the 75 reported cases were suspected prior to operation or death.

4 True aneurysm is usually asymptomatic. A few patients have complained of pain in the flank. The cardinal symptoms of false aneurysm are hematuria, pain and tumefaction in the flank. The pathognomonic signs—pulsation and a systolic bruit—have been present in 7 cases. The presence in the x-ray film of a ringlike shadow, with a dense periphery disrupted in one portion and a rarefaction of the center in the kidney or hilar region, is suggestive of a renal aneurysm.

5 The treatment is surgical. In the literature, all patients presenting symptoms who were not operated on died. Of the 29 patients subjected to nephrectomy, 26 survived. Of 37 patients who underwent operation, 8 died—an operative mortality of 21 per cent.

ABSTRACT OF DISCUSSION

DR HERBERT H. HOWARD, Boston. There is little that I can add in the discussion of this paper. I should like to reemphasize that trauma and syphilis per se play an insignificant part in the etiology of this particular aneurysm. Arteriography by aortic injection was not mentioned by the authors in their methods of diagnosis and it seems to me that this is an important adjunct. Santos of Lisbon in 1930 was the first to publish a description of this procedure and he used a 100 per cent solution of sodium iodide. In the March 1942 issue of *Surgery, Gynecology and Obstetrics* Nelson of Seattle published an article on arteriography of abdominal organs by aortic injection using an 80 per cent solution of sodium iodide. I have used it on two occasions without any ill effects. If it is ever my good fortune to diagnose and operate in another case of true aneurysm of the renal artery I shall have as an assistant a cardiovascular surgeon to see if the aneurysm, provided it is extrarenal, cannot be operated on and the kidney saved. If one reviews the literature of true aneurysms of the renal artery, and I am speaking now of the extrarenal type, one will find the kidney to be a normal one.

DR O. A. NELSON, Seattle. My associates and I have not encountered any aneurysm of the renal artery but we have been astounded by the large number of aneurysms, most of them found in sites that were unexpected, in our work. One of the things that was encountered frequently was blockage of one or more of the large vessels, particularly in the kidneys. I am sure that arteriography will be a procedure too that will

make the diagnosis at least of aneurysm of the renal artery very easy to make. The procedure is not as hazardous as one might think.

DR VICTOR D. LESPINASSE, Chicago. I have been looking for an aneurysm of the renal artery and never found one. I am interested in doing a reparative operation on the artery. I think that if the conditions are right it can be done. It is a feasible operation but the condition that one must have is normal arterial wall or relatively normal arterial wall. If the wall is calcified it cannot be manipulated. One cannot sew it. It won't hold. Then one must have a method of blood control while one is making the repair. Only one clamp is needed. It isn't like an aneurysm of the femoral. But I think that point should be in anybody's mind when one operates in 1 of these cases to try to do a reparative operation and not a destructive one. If one has that in mind I think that sooner or later somebody will be able to repair these artery aneurysms and save the kidneys.

DR OSWALD S. LOWSLEY, New York. I am overwhelmed with joy to see our sister republics here in the audience and grouped on the table with us. I think this is very significant. I wish to commend my young associate Dr. Cannon on the splendid job that he did on this paper, which he did and I am lending my name to it. A few points I wish to emphasize. One thing in which we take a considerable amount of pride is that our resident, at that time Dr. Forsythe, made the diagnosis, and this is only one of twelve diagnoses that have been made preoperatively in the history of the world. It is rare, of course, there being only 75 cases in all the medical literature. In this particular case there was no opportunity for repair. We had it in mind at the time of operation and we hope that we shall see others and have an opportunity to repair, doing a short circuit, excising the aneurysm and leaving the artery but in this particular case it was not possible. I came home from the meeting of the French Urological Association with enthusiasm about arteriography, and I got Dr. Henline interested. Dr. Henline operated on 16 dogs, all of which died. Now we know that a young, healthy dog will die much easier than a sick human being. If you can get by with any operation on a young, healthy dog, you can get by with that operation on a sick human being. Dos Santos told me that at that time he had done about 150 operations and only 1 patient died. This method is safe. Dr. Nelson has evidently found out how to make it safe.

Orr's Plaster Technic—Toward the end of the war of 1914 to 1918 the American surgeon Winnett Orr made an observation which was destined to have far reaching results. Among the soldiers who were admitted to his hospital he noticed that those whose wounds had been enclosed in a plaster cast to facilitate transport to America were generally in a better condition than others who had been treated by the orthodox methods of the time. In spite of the bacterial infection present in all these cases, the granulation process was proceeding undisturbed, the patients showed no clinical sign of sepsis and the majority were doing well. This observation led him, after the war, to develop a technic of treating infections of the extremities and in particular osteomyelitis, by the provision of drainage and complete immobilization of the limb in plaster. He also advocated this technic for infected compound fractures and later suggested that it could be applied to fractures at an early stage. His readiness to appreciate the importance of immobilization by plaster was due to his experience as a pupil of John Ridlon, who, as he writes in the preface to Orr's book *Osteomyelitis and Compound Fractures* (1929) for forty years had immobilized all his operative wounds of the soft tissues, as well as of bones, with plaster of paris casts and then watched the patients, not the wound—Trueta, Josep. *The Principles and Practice of War Surgery*, St. Louis, C. V. Mosby Company, 1943.

DIVERTICULA OF THE COLON

PROCTOSCOPY AS AN AID IN THE DIAGNOSIS AND
DIFFERENTIAL DIAGNOSIS

RAYMOND J. JACKMAN, M.D.

AND

LOUIS A. BUIE, M.D.

ROCHESTER, MINN.

Diverticula of the colon are pouchlike protrusions from the wall of the bowel which are classified as congenital and acquired. Congenital or true diverticula, of which Meckel's diverticulum is an example, are rare. Their distinguishing characteristic is that the wall of the sac contains all the normal coats of the bowel, from which the diverticulum originates. False or acquired diverticula, with which this paper is concerned, are of much more common occurrence, and their distinguishing characteristic is that the pouch is made up of mucosa and serosa, the muscular layers are absent.

These outpouchings of the colon have been a subject of discussion for a century and a half. The condition was formerly looked on as of rare occurrence, but now it is commonly encountered. Very little has been

added to Cruveilhier's¹ account, which was published in 1849. We hope, herewith, to make a small contribution.

SPECIAL VALUE OF
PROCTOSCOPIC
EXAMINATION

Although the diagnosis of diverticula of the colon is dependent primarily on roentgenologic studies,

Fig. 1—Diverticulum showing inspissated piece of stool in it.

proctoscopic examination is of more value than may be thought. It may be of use for instance when a condition which roentgenologically appears to be carcinoma is actually diverticulitis. The roentgenologic filling defect following a barium sulfate enema in the presence of diverticulitis of the colon usually is described as relatively long. This is not always true, however, and if the filling defect is short the condition may be confused with carcinoma because the other roentgenologic findings in the presence of carcinoma are similar to those of diverticulitis, especially when the carcinoma is associated with inflammation. Proctoscopic examination may make the diagnosis possible.

Not uncommonly, moreover, differential diagnosis between a malignant condition and inflammation is difficult or impossible, even at the time that the surgeon explores the abdomen. In those cases in which colostomy has been performed, proctoscopic examination of the distal segment of bowel by way of the anus as well as examination of both proximal and distal segments through the colonic stoma is of estimable value in determining the degree of the inflammatory process and the amount of obstruction in the

region of inflammation. The surgeon must be informed concerning these matters before he attempts closure of the colonic stoma.

Proctoscopic Signs—In 1939 one of us² reported five proctoscopic signs which may determine, or lead to the strong suspicion of the presence of diverticulosis or diverticulitis. The signs enumerated are as follows:

1 Limited mobility of a segment of bowel which is normally freely movable. Relative immobility of a segment of bowel alone is insufficient evidence on which to base a diagnosis of diverticulitis, but when this is associated with one or more of the other irregularities mentioned, immobility forms strong supportive evidence. A fixed or retroverted uterus and pelvic inflammatory disease may interfere with, or even prevent, complete proctoscopic examination. It is not difficult to distinguish this type of immobility from that which is observed in the sigmoid from which inflamed diverticula originate. In those instances in which the interference is caused by pelvic disease or a fixed, retroverted uterus the obstruction is confined to the rectum. Usually in diverticulitis the rectum is unobstructed and little difficulty is experienced with the examination until the sigmoidal segment is reached.

2 Angulation of the bowel. The lumen may turn sharply at the point at which it is immobilized by diverticulitis, and advancement of a proctoscope of average caliber beyond the angulation may be difficult or impossible.

3 Reduced lumen and adherent mucosal folds. The contracture of the lumen is due to impingement on the wall of the bowel and as the lining membrane is crowded together the mucosal folds become adherent. The mucosa may be edematous. Often additional information can be gained by using an instrument of smaller caliber.

4 Sigmoidal sacculation. This peculiarity is characterized by the appearance of shallow pouches which extend partially or wholly around the wall of the bowel. The pouches are separated by ridgelike elevations, usually they are observed in a mobile sigmoid which bears no evidence of inflammatory disease. Frequently these sacculations are found in the course of postmortem examination of elderly persons. Spriggs and Marver³ after making roentgenologic studies of the colon described a prediverticular state in which normal segmentation of the bowel is absent and is replaced by a ragged outline of little convex irregularities. It is doubtful whether the prediverticular stage of Spriggs and Marver is identical with the sacculation seen in proctoscopic examination and so frequently observed in postmortem examination of elderly persons.

5 Seeing the diverticula (fig. 1). One or more diverticula are actually seen more frequently than is generally believed. Whenever it is possible to discover a diverticulum, however, inflammation seldom is present.

STUDY OF FOUR HUNDRED CASES

The records of 400 consecutive patients of the Mayo Clinic who were found to have diverticula of the colon were studied in order to compare the proctoscopic with the roentgenologic findings and in this connection, to determine the value of the signs enumerated. Of these patients, 213 (53 per cent) were males and 187 (47 per cent) were females. Their average age was 56 years.

From the Section on Proctology, Mayo Clinic.
Read before the Section on Gastro-Enterology and Proctology at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J., June 10, 1942.
¹ Cruveilhier, Jean. *Traité d'anatomie pathologique générale*. Paris: J. B. Baillière, 1849, vol. 1.

² Bue, L. A. Diverticula of the Colon. *New England J. Med.* 221: 593-598 (Oct. 19) 1939.
³ Spriggs, E. I. and Marver, O. A. Intestinal Diverticula. *Quart. J. Med.* 19: 134 (Oct.) 1925.

In 150 (38 per cent) of the 400 cases proctoscopic examination was not performed and the diagnosis was made from clinical and roentgenologic studies only (table 1). In 8 (2 per cent) of the 400 cases roentgenologic examination of the colon was not carried out and the diagnosis was made by clinical and proctoscopic examinations only. The diverticula were seen at proctoscopic examination in all 8 cases. It is with the remaining 242 cases (60 per cent) of the 400 cases in which both sigmoidoscopic and roentgenologic studies of the colon were carried out, that this study is primarily concerned.

Of the 242 cases, results of sigmoidoscopic examination were negative in 82 (34 per cent) (table 2). In the remaining 160 cases (66 per cent) of 242 some evidence of the existence of diverticula was ascertained by sigmoidoscopic examination or the diverticula were seen.

In 35 (22 per cent) of the 160 cases diverticula were observed on sigmoidoscopic examination and their presence was confirmed by roentgenologic studies of the colon (table 3). In an additional 72 (45 per cent) of the 160 cases the proctoscopist reported the presence

Fig 2—Portion of resected sigmoid showing sacculations, diverticula and strong perisigmoidal inflammatory reaction.

of sacculations of the sigmoid and the roentgenologist confirmed his suspicion as to the presence of diverticula. Parenthetically, it can be said that in 18 of the 35 cases in which diverticula were seen sacculations were seen also, making a total of 90 cases in which sacculations were observed (fig 2). In the 53 cases (33 per cent of the 160) which remained after the 35 and 72 had been subtracted, there was other sigmoidoscopic evidence which strongly suggested the presence of diverticula of the sigmoid, and roentgenologic studies of the colon confirmed the diagnosis. These findings were immobility, sharp angulation, narrowing of the lumen, mucosal edema, extrarectal mass and inability to pass the proctoscope the average distance. Although these findings may exist singly, they usually exist in combination.

It is interesting to observe that in 3 of the cases of colonic diverticula sacculations were noticed on proctoscopic examination, but the primary roentgenographic studies failed to reveal the presence of diverticula. From one to six years later roentgenologic studies of the colon revealed the presence of diverticula. It is possible, in many of the cases in which sacculations are found on proctoscopic examination, and in which diverticula cannot be demonstrated by roentgenologic studies, that these sacculations may represent a pre-diverticular stage.

PROCTOSCOPY AFTER COLOSTOMY

Early in this paper we pointed out the value of proctoscopic examination following colostomy. With present day medical management the use of colostomy or other emergency operation for relieving obstruction

TABLE 1—Four Hundred Cases in Which Diverticula Were Found

of the lower part of the bowel has decreased considerably. There are, however, definite indications for colostomy, namely (1) acute obstruction which has failed to respond to medical management, (2) sigmoidovesical fistula and (3) extensive abscess formation. It is in these complicated conditions that preoperative diagnosis by proctoscopy is of great value.

Special Study of Fifty Cases—We selected for special study 50 patients on whom colostomy had been performed because of an obstructing lesion in the lower part of the bowel and in relation to which a preoperative diagnosis was impossible. The nature of the obstruction was indeterminate for the following reasons: 1. The problem was of an emergency character. Many

Proctoscopic	37	74
Pathologic	13	26
Total	50	100

patients were too sick to permit necessary diagnostic examinations to be made. 2. The attempt to relieve obstruction by medical management failed. 3. Colostomy had been performed as an emergency elsewhere. Thirty-one of the patients had been operated on at the clinic and 19 elsewhere. In many of these cases, even though the abdomen was explored at the time of colostomy, the surgeon was unable to determine the nature of the obstruction. Proctoscopic examination

by way of the colonic stoma or anus was responsible for making a diagnosis in 37 (74 per cent) of these cases (table 4). In many cases the examination had to be repeated several times, at intervals of several days or weeks, and often it was found that a loop of bowel which was found to be inaccessible at one examination because of fixation and inflammation had become, at a subsequent examination, more mobile, thus permitting more satisfactory examination. In the remaining approximately one fourth of the cases the diagnosis was made by the pathologist after the diseased segment of bowel had been resected (fig 3).

SUMMARY

A study of 400 cases of diverticula of the colon has been made. The diagnosis was made clinically and by roentgenologic examinations in 150 of the cases and clinically and by proctoscopic examination in 8. In the remaining 242 cases both roentgenologic studies of the colon and sigmoidoscopic examinations were performed. In 160 of these 242 cases sigmoidoscopic examination revealed or gave some evidence of the presence of diverticula. Of these 160 cases, in 35 the proctoscopist saw diverticula (sacculations also in 18 of the 35), in 72 sacculations and in 53 one or more of the following evidences: immobility, sharp angula-

ABSTRACT OF DISCUSSION

DR JOHANNES PLSSEL, Trenton, N. J. At the Graduate Hospital we don't see these diverticula quite as frequently as do Drs. Jackman and Buie. We do, however, notice edema. Our experience is that edema below malignant lesions is rare, and when it occurs we suspect an inflammatory lesion. We have found a longer proctoscope helpful, that is, preoperatively. We frequently use a 14 or 16 inch proctoscope in an attempt to view this area. I should like to mention the use of some form of atropine or belladonna for a day or two previous to a second examination. This frequently will at least diminish the amount of spasm that one encounters on the first examination and one can get a better impression of the lesion.

DR JOHN C. M. BRUST, Syracuse, N. Y. The menace of malignancy is constantly present and must if possible be excluded. Medical students are far too often taught that diverticulitis is merely "left sided appendicitis." The frequency of bladder symptoms, rare instances of sudden profuse rectal bleeding, absence of fever and many other features combine to make diverticulitis a complex and often bizarre picture. One brief case report will illustrate many of these points. A man aged 52 had rectal pain and inability to void. The duration of illness was thirty hours. Catheterization was performed and 950 cc of concentrated urine obtained. The prostate felt normal. There was induration and tenderness felt through the posterior rectal wall in the hollow of the sacrum. The abdomen was soft and the bowel history was that of prolonged constipation. The day after admission there was increasing evidence

FIG. 3.—Method of examination with sigmoidoscope after colostomy. *a* Sigmoidoscope inserted by way of anus and rectum leaving catheter in place to indicate that that much of the bowel was examined. *b* Sigmoidoscope inserted by way of stoma; catheter in rectum indicating that the distal segment has been completely examined. *c* Examination of the proximal loop by way of stoma.

tion, narrowing of the lumen, mucosal edema, extrarectal mass or inability to pass the proctoscope the average distance.

In another group of 50 cases in which colostomy had been performed as an emergency measure because of an obstructing lesion in the lower part of the bowel, and in which the preoperative diagnosis was indeterminate, a study was made in order to learn the value of sigmoidoscopic examination performed by way of the anus or the colonic stoma. Sigmoidoscopic examination was responsible for the diagnosis in 37 of the 50 cases.

CONCLUSIONS

1 Roentgenology provides the most valuable single aid in establishing the diagnosis of diverticula of the colon.

2 The most valuable single proctoscopic finding, aside from actually seeing the diverticula, is the presence of sacculations.

3 The proctoscopic findings of immobility of the bowel, angulation, mucosal edema, narrowed lumen and extrarectal mass are of value, but it should be remembered that some of these signs are observed in other diseases of the pelvic organs.

4 Our study would indicate that proctoscopy is a valuable adjunct to clinical and roentgenologic findings in determining the nature of obstructive lesions in the lower part of the bowel.

of fluctuation between the sacrum and the rectum. No intrinsic lesion was seen by sigmoidoscopy for 20 cm. This procedure was done under caudal anesthesia because of rectal pain. A stab wound was made through an operating microscope and a hemostat passed behind the rectum through the rectal mucosa. A moderate amount of foul pus was obtained and from this retrorectal abscess cavity we obtained hundreds of tiny fecaliths about the size of grape seeds. A barium sulfate enema with a roentgenogram of the colon revealed narrowing at a point in the lower sigmoid but it did not appear malignant. No diverticula were seen. We felt that a diverticulum had perforated and an abscess had formed. The contents of the diverticulum could account for the innumerable small fecal pellets. Despite sulfamidate therapy and general supportive and dietary measures, he continued to have retrorectal tenderness and a persistent discharge of pus. Twelve days after admission the abdomen was opened. An infected mass was found surrounding the lower sigmoid. The inflammatory reaction was pronounced. It did not feel or appear malignant. A double barreled colostomy was performed. Hot irrigations were begun. Sulfamidate therapy was continued. We kept this man under observation and used a proctoscope at frequent intervals. We believe this was a perforation of a solitary diverticulum in the lower sigmoid. The severe reaction prevented any actual demonstration of an opening by proctoscopy but we could say with assurance that no malignancy existed. We rarely see diverticular openings if an acute inflammatory process is present. The other signs, namely sigmoidal sacculations, limited mobility, sharp angulation and reduced lumen, are of dubious value. Sigmoidoscopy properly performed is rarely productive of severe pain. One exception is acute diverticulitis.

THE PREVENTION OF RENAL OBSTRUCTION DURING SULFADIAZINE THERAPY

CHARLES L. FOX JR., M.D.

OLE J. JENSEN JR., M.D.
NEW YORK

AND

LIEUTENANT GILBERT H. MUDGE
MEDICAL CORPS, ARMY OF THE UNITED STATES

In the recent literature there are many reports of renal obstruction during therapy with sulfapyridine, sulfathiazole and sulfadiazine. This complication is attributed to the poor solubility of these drugs and their acetyl derivatives.¹ It is important to realize that the sulfonamide compounds differ considerably in their solubility. Sulfanilamide, for example, is a relatively soluble drug, and renal complications are rare. Sulfapyridine, sulfathiazole, sulfadiazine and their acetyl forms, on the other hand, are relatively insoluble² and renal complications occur frequently. If the solubility of these drugs in urine could be increased, this complication might be prevented. The data presented here will show that the solubility of sulfathiazole and sulfadiazine and their acetyl forms can be increased and renal precipitation thereby prevented.

The first procedure in our studies was to determine the solubility of sulfathiazole and sulfadiazine and their acetyl derivatives in normal human urine over the p_H range 5.0 to 8.0.³ This proved to be the key to the problem, as seen clearly in figure 1, there is a very sudden and decided increase in the solubility of these substances as the urine is made alkaline. The explanation of this phenomenon is that these drugs and their acetyl derivatives are weak acids which ionize and form soluble salts in an alkaline medium⁴ (e.g. sodium sulfadiazine and sodium acetyl sulfadiazine). The question then arises: How much soluble salt formation can occur in urine within the physiologic p_H range? As the p_H is raised from 5.0 to 7.0 (fig. 1) there is little salt formation and the solubility in urine is not appreciably increased, from p_H 7.0 to 8.0, however, there is extensive salt formation and the solubility of sulfathiazole and sulfadiazine, both free and acetyl, is greatly increased.⁵ In the case of sulfapyridine and its acetyl

form, on the other hand, extensive salt formation does not occur until p_H 9.0 and 10.0 respectively are reached—beyond the p_H range of urine, this accounts for the failure of alkali therapy to prevent renal precipitation of this drug. With sulfanilamide, salt formation does not occur until p_H 10.6 is reached but, in contrast to the preceding drugs, it is a relatively soluble substance.

In vivo this phenomenon has also been investigated in dogs.⁶ In these experiments it was found that sulfadiazine crystalluria was produced when acid urine was excreted after the administration of ammonium chloride, conversely, crystalluria was prevented by maintaining the urine alkaline by the administration of sodium bicarbonate. Furthermore, it was noted that the p_H of the urine closely regulated the concentration of sulfadiazine that was excreted in solution in the urine, i.e., low levels were obtained in acid urine and high levels in alkaline urine during constant drug dosage.

In a study of the pathogenesis of complications in the urinary tract it is important to consider the concentration at which the drug is excreted in the urine. While blood levels of about 10 mg per hundred cubic centimeters are obtained in patients receiving 4 to 6 Gm a day, the level that is obtained in the urine varies from 100 to 300 mg per hundred cubic centimeters. Increasing the urinary output from 1,000 to 2,000 cc a day might double the quantity of sulfadiazine in solution but raising the p_H from 6.5 to 7.5 will permit more than a tenfold increase in solubility.

In view of the in vitro experiments indicating the greatly increased solubility of sulfathiazole, sulfadiazine and their acetyl derivatives in alkaline urine and the animal experiments substantiating this, it was decided to employ this method in the massive sulfadiazine therapy of subacute bacterial endocarditis in the hope that the renal complications with oliguria reported by Dick⁷ might be prevented.

CLINICAL PROCEDURE

Two patients whose diagnosis of subacute bacterial endocarditis was established were selected for massive sulfadiazine therapy. To induce diuresis of an alkaline urine, sodium bicarbonate⁸ and large amounts of fluids were given prior to the administration of sulfadiazine. The p_H of each specimen was measured as soon as voided with a Beckman p_H meter and if the p_H of the urine had dropped below 7.5 additional alkali was administered. Each specimen was centrifuged and the

8. Some potassium bicarbonate was given to prevent the accumulation of excess sodium ion and consequent edema. The potassium salt however produced nausea and vomiting and was discontinued. No edema or alkalosis resulted from the large amounts of sodium bicarbonate administered.

sediment examined microscopically for drug crystals. When crystals were observed a rough quantitative estimate of the degree of crystalluria was obtained by determining the concentration of sulfadiazine in the sediment and in the supernatant fluid.⁹ When these differed by more than 5 per cent crystalluria was grossly

The Renal Function Before and After Massive Sulfadiazine Therapy

Case	Maximum Specific Gravity		Albumin		Crystals or Blood Cells		P S P Excretion in 2 Hours		Serum Urea Nitrogen Mg./100 Cc	
	Before	After	Before	After	Before	After	Before	After	Before	After
1	1.024	1.020	0+	0+	0	0	6.5% in 200 cc	60% in 160 cc	17	1*
2	1.020	1.024	0	0	0	0	70% in 240 cc	80% in 290 cc	10	2*

visible. Renal function tests were done before and after treatment, the specimens were tested for albumin and the specific gravity was measured.

REPORT OF CASES

CASE 1—R W, a white man aged 34 had fever, night sweats, malaise and weight loss of two months' duration, a history of rheumatic fever and chorea, signs of mitral stenosis and insufficiency and aortic insufficiency. Blood cultures contained a strain of *Streptococcus viridans*. The only signs of cardiac decompensation were a slightly enlarged liver and moderate dyspnea on exertion. There was no anemia. Before admission to the hospital he had received sulfathiazole in normal therapeutic amounts for two weeks with slight symptomatic improvement. Renal function tests were normal and are shown in the accompanying table.

Preparatory alkali therapy consisted in the oral administration of 54 Gm of sodium bicarbonate daily. After five days, however, this was insufficient to make the urine persistently alkaline, therefore 12 Gm of potassium bicarbonate was given on the day before and on the day of treatment. At the start

Fig 2 (case 1)—Summary of course of therapy. Although large quantities of sodium bicarbonate were given certain specimens of urine became acid. The minimum daily output of urine was 775 cc. The blood and urine sulfadiazine levels are shown as well as the transient rise in serum urea nitrogen. The highest sulfadiazine levels in the urine did not greatly exceed the levels found during routine therapy.

of therapy the urine pH was 7.65. Fluids were forced and the day before treatment the patient voided 5730 cc. Twenty-five Gm of sodium sulfadiazine (0.454 Gm per kilogram of body

weight) was administered intravenously in 500 cc of distilled water over a period of one hour and twenty minutes. A serum level taken one hour after the infusion had been terminated was 695 mg of sulfadiazine per hundred cubic centimeters (fig 2). For several hours thereafter the patient had frequency and burning on urination with moderately severe pain in the flank, hematuria and crystalluria. It is noteworthy that at the time these symptoms began the urine pH had fallen, varying from 6.6 to 7.46, and that the urine sulfadiazine concentration was 639 mg per hundred cubic centimeters, which is well above the solubility found in vitro at the pH of the individual voiding (fig 1). At the same time the specific gravity of the urine varied from 1.002 to 1.006. Larger doses of potassium bicarbonate were given and the urine pH was raised, varying from 7.4 to 8.1 for the next day, with slight crystalluria persisting for that day. Sodium bicarbonate was then given intravenously on the following days. There was no oliguria, as shown by a minimum daily volume of urine of 775 cc. This is in sharp contrast to the twenty-four urine volume of 15 cc reported by Dick.¹⁰ For the following three days the patient had gross hematuria and 2 to 3 plus albuminuria. Microscopic hematuria and 1 to 2 plus albuminuria persisted for

Fig 3 (case 2)—Summary of first course of therapy. The administration of large amounts of sodium bicarbonate kept the urine alkaline. The minimum daily output of urine was 860 cc. The blood and urine sulfadiazine levels are also shown together with the transient rise in serum urea nitrogen. The highest sulfadiazine levels in the urine did not greatly exceed those found during routine therapy.

three days more. The serum urea nitrogen rose to 64 mg per hundred cubic centimeters on the fourth day and then gradually returned to normal. During the period of treatment the patient experienced slight nausea and vomiting, his temperature remained elevated and there were many embolic phenomena, whereas previously there had been but few. The blood cultures (with para-immuno benzoic acid added to the mediums) were negative for one week and then again became positive.

CASE 2—B B, a white schoolgirl aged 16 had fever, malaise and an occasional sore finger tip for two months, a history of rheumatic fever, signs of mitral stenosis and insufficiency and aortic insufficiency, blood cultures yielded a strain of *Streptococcus viridans*. There was no evidence of cardiac decompensation. Prior to admission to the hospital she had received sulfadiazine in the usual doses for a total of two weeks, with temporary symptomatic improvement. There was no anemia and the renal function tests were normal, as shown in the table.

Preparatory alkali therapy consisted in the oral administration of 45 Gm of sodium bicarbonate and 80 Gm of potassium bicarbonate for two days. At the start of therapy the pH was

9. The sulfonamide levels were determined by the method of Bratton and Marshall (A New Coupling Component for Sulfanilamide Determination J Biol Chem 128 537 [May] 1939) with the Klett-Summerson photoelectric colorimeter.

775 Fluids were forced and a diuresis of 2150 cc was obtained. Thirty Gm of sodium sulfadiazine (0.52 Gm per kilogram of body weight) was given intravenously in 600 cc of distilled water over a period of one and one-half hours. One hour after the infusion was terminated the serum sulfadiazine level was 138 mg per hundred cubic centimeters (fig 3). The patient had no specific urinary symptoms but experienced slight discomfort in the left upper quadrant of the abdomen similar to that which she had noted before the administration of sulfadiazine. Nausea and vomiting appeared after the termination of the infusion and lasted one week. The daily fluid balance was maintained by the administration of parenteral fluids. There was gross hematuria and 2 to 3 plus albuminuria for three days. The p_H of the urine remained above 7.5 and there was no oliguria—the minimum daily volume of urine was 860 cc. Sodium bicarbonate (10 Gm a day) was given intravenously for the next four days in the late evening in an attempt to counteract the usual acidity of the early morning specimens. Microscopic hematuria and 1 plus albuminuria were noted in the next three days. A rare sulfadiazine crystal was seen in only one of the urine specimens during the week following the infusion of the drug, and during this period all of the urine sulfadiazine levels fell within the *in vitro* solubility curve (fig 3). The serum urea nitrogen was 36 mg per hundred cubic centimeters on the fourth day after treatment and returned to normal on the seventh day. Renal function studies after massive sulfadiazine therapy were normal (table 1).

Following the massive intravenous dose of sulfadiazine the patient had a normal temperature and negative blood cultures for one week, but then fever reappeared and the blood cultures became positive. Although the single massive dose had not been followed by oliguria, there was definite evidence of temporary disturbance of renal function. Accordingly smaller daily doses of the drug were given. There was no reaction to a trial dose of 1 Gm of sulfadiazine and, after fluids had been forced and the urine had been made alkaline, 10 Gm of sodium sulfadiazine was given intravenously (fig 4). A serum level of 383 mg per hundred cubic centimeters was obtained, and on the following day 10 Gm was again given intravenously, and one hour later the serum level was 545 mg per hundred cubic centimeters. Transient hematuria and albuminuria followed both infusions. The serum level fell rapidly and it was therefore decided that a uniformly higher serum level could be maintained with large divided oral doses. After another infusion of 5 Gm of the sodium salt, the patient was maintained on daily doses of from 8 to 20 Gm of sulfadiazine for seventeen days the average dose being 13.7 Gm a day (0.25 Gm per kilogram of body weight). The average serum sulfadiazine level was 25 mg per hundred cubic centi-

of the first voiding each morning, which ranged from 6.4 to 7.4 (average 7.0), despite the administration of as much as 3.6 Gm of sodium bicarbonate at 2 a.m. During this period there was gross crystalluria on six occasions but no flank pain, dysuria or hematuria occurred. The serum urea nitrogen was not elevated and repeated urea clearance tests were normal. On the seventeenth day of therapy crystalluria with hematuria, flank pain and dysuria developed. At this time the level of sulfadiazine in the urine was 445 mg per hundred cubic centimeters but the p_H was only 7.0 which is not high enough to keep this concentration of sulfadiazine in solution (fig 1). Sulfadiazine was stopped but the administration of sodium bicarbonate was continued and the hematuria and flank pain subsided in one day. The urine volume fell to 750 cc for one day but there was no nitrogen retention. Following this episode an intravenous pyelogram showed normal excretion from both kidneys without filling defects. During the seventeen day period the patient was afebrile but following cessation of the drug fever reappeared and the blood cultures once again became positive.¹⁰

COMMENT

It is apparent that in these 2 cases renal obstruction during massive sulfadiazine therapy was prevented. The role of p_H in preventing crystalluria is clearly demonstrated by figure 5, which relates the p_H and drug level of each specimen to crystalluria. It has been shown that the solubility of sulfadiazine *in vitro* in human urine can be increased many times by increasing the p_H . Figure 5 shows that this applies also to human urine excreted during therapy. In comparing these specimens with the *in vitro* solubility curve, it will be seen that 48 per cent of the specimens in which the p_H was lower than (to the left of) the solubility curve contained gross or microscopic crystals, whereas only 7.2 per cent of the specimens in which the p_H was higher than (to the right of) the solubility curve contained microscopic crystals. Of these, one half were voided directly following a specimen that contained gross crystals. It is also significant that in case 1 the urine p_H was lowered and crystalluria occurred when the *in vitro* solubility was exceeded.

This relationship between the p_H of the urine and the solubility of sulfadiazine is vividly demonstrated by the fact that a specimen containing 788 mg per hundred cubic centimeters free (60 times the water solubility) and 192 mg of acetyl sulfadiazine per hundred cubic centimeters (13 times its water solubility) was voided without occurrence of crystals. When the p_H of this specimen was lowered 0.2 p_H unit by addition of a small amount of acid, the clear specimen immediately became milky turbid as crystals of sulfadiazine appeared.

¹⁰ Subsequently, with average doses of 4 to 6 Gm daily the blood cultures became negative.

Fig 4 (case 2)—Summary of therapy with large daily doses. More constant high serum levels of sulfadiazine resulted from divided oral dosage. Higher urinary levels (crystal free) were obtained with this form of therapy. The large daily doses of sodium bicarbonate needed to keep the urine alkaline are shown. The serum urea nitrogen did not become elevated.

meters and the daily urine volume varied from 1200 to 3300 cc with the exception of the final day of treatment. The average daily intake of sodium bicarbonate was 121 Gm. There was no edema or clinical evidence of alkalosis and the serum carbon dioxide combining power varied from 53.2 to 72.7 volumes per cent. The urine p_H was maintained above 7.5 with the exception

There are several practical points which may be mentioned. The "routine" use of alkalis will probably not keep the urine alkaline and avoid crystalluria. The quantity of alkali needed should be governed primarily by the p_H of the urine (which should be measured frequently) and not by the amount of sulfadiazine given. Since the morning specimen has the lowest p_H and the highest concentration of sulfadiazine, this seems to be the specimen most apt to contain crystals.¹¹ Thus of 22 specimens containing crystals, 17 were morning specimens. For this reason it is advisable to administer alkali at night to counteract this tendency.

Although previous papers have suggested the advisability of adjuvant alkali therapy in patients receiving the sulfonamide compounds, this has not been generally accepted as a method of preventing urinary complications. Two reasons become evident. When used with sulfapyridine, alkalis do not and cannot prevent urinary complications because they do not sufficiently increase the solubility of sulfapyridine and acetyl sulfapyridine within the physiologic range of urinary p_H to prevent renal precipitation. Secondly with sulfathiazole and sulfadiazine, the usual quantities of alkali given are

Fig. 6—Diagrammatic representation of the renal excretion of the sulfonamide compounds. As the urine is formed the concentration of the sulfonamide may be increased thirty times or more. Precipitation will depend on the solubility of the particular drug at the concentration and p_H resulting from urine formation.

insufficient to maintain the urine consistently alkaline, in the 2 cases reported here large amounts of bicarbonate were needed to keep the urine at p_H 7.5.¹² It is important to realize that as these drugs are excreted by the kidney (fig. 6) a concentration of 10 mg per hundred cubic centimeters in the blood may be increased to 300 mg per hundred cubic centimeters in the urine as a result of reabsorption of water by the tubules. In addition base is also reabsorbed and the p_H may be lowered from that of the blood (7.4) to as low as 5.5, commonly found in the urine. By thus lowering the p_H in the case of sulfathiazole, sulfadiazine and their acetyl forms, the soluble salts are converted to the relatively insoluble acids, and precipitation takes place. The function of the alkali is to prevent this fall in p_H during the formation of urine.

These studies also suggest a most valuable aid in the lavage therapy of acute or impending renal blockage. Instead of using warm water or warm saline solution in which these drugs are but very slightly soluble sodium bicarbonate or sodium carbonate solution should be used to dissolve the crystals, the more concentrated the solution, the greater the solvent action.¹³

11 This was also observed during routine therapy with sulfadiazine (Anderson D and Rose H M. Unpublished data).

12 Additional alkalis are also needed when sulfadiazine is administered by mouth in the form of the sodium salt. Apparently a large excess of alkali is required to neutralize the usual acidity of the urine. Although the possibility of producing alkalosis and edema might be an objection to the simultaneous use of large amounts of alkali, none was detected in these and numerous other patients to whom similar amounts of alkali were given.

13 It is of interest to note that just recently Wright and Kinsey described large orange yellow crystals in their case 4 which dissolved readily when the urine was alkalinized.

SUMMARY

1 There is great variation in the urinary solubility of sulfadiazine, sulfathiazole and their acetyl forms over the physiologic p_H range.

2 Since the solubility of these drugs is greatly increased in alkaline urine, maintenance of a consistently alkaline urine was tried as a means of preventing renal obstruction during sulfadiazine therapy.

3 Two patients with subacute bacterial endocarditis were given massive doses of sulfadiazine and with certain exceptions their urine was maintained consistently alkaline with large doses of bicarbonate (10 to 20 Gm daily). No diuresis or edema resulted.

4 High concentrations of sulfadiazine were held in solution in alkaline urine, oliguria and renal obstruction were prevented. Crystalluria occurred in those urine specimens in which the p_H fell below the in vitro solubility limits.

5 The quantity of bicarbonate to be given should be judged by the p_H of the urine. To maintain sulfadiazine in solution during full therapeutic dosage, a p_H of 7.5 or higher is essential.

6 When alkaline urine is voided with high concentrations of sulfadiazine in solution, decreasing the p_H slightly will immediately precipitate the drug.

7 In the renal (pelves and ureters) lavage therapy of renal obstruction caused by one of the sulfonamide compounds, alkaline bicarbonate or carbonate solutions are recommended since these will dissolve drug crystals much better than warm water or isotonic solution of sodium chloride. Utilization of this information in routine therapy with sulfathiazole and sulfadiazine in average doses would remove the hazard of their renal complications.

Clinical Notes, Suggestions and New Instruments

ESTIVO AUTUMNAL MALARIA WITH FRONTAL LOBE SYNDROME

MAJOR NORMAN Q. BRILL
MEDICAL CORPS ARMY OF THE UNITED STATES
AND
CAPTAIN VICTOR L. PELLICANO
MEDICAL CORPS ARMY OF THE UNITED STATES

Since the mobilization program started there has been a shifting of large numbers of men not only within the country but to many points throughout the world. With this wartime flow of population and with extension of the war to more and more tropical and subtropical countries the incidence of malaria can be expected to increase steadily.

Many physicians in the armed forces serving in localities far removed from their home have had limited experience with the disease and have had little opportunity to observe the varied fashions in which it may manifest itself. Members of the medical profession in military service must be familiar with the protean manifestations of malaria so that their function to preserve the fighting strength of our forces will not be impaired.

The following case is reported to illustrate that malaria may manifest itself primarily by a syndrome of disease of the frontal lobe of the brain. We have been unable to find a similar case recorded in the literature, though many cases of cerebral malaria have been described.

REPORT OF CASE

W. S., a white soldier aged 24, a native of Texas, had been in the Army for six months serving with an engineer battalion.

Released for publication by the War Department Manuscript Board which assumes no responsibility other than censorship for the contents of this article.

when he became ill. On Oct 15, 1941, during the Carolina maneuvers, he was admitted to an evacuation hospital complaining of severe low backache, pain in the eyes and fever of three days' duration. The patient was dull and confused. He was transferred to the Station Hospital at Fort Bragg, North Carolina, the following day with a diagnosis of influenza and possible encephalitis.

On physical examination the soldier was well developed and well nourished and appeared acutely ill. The skin was flushed and hot. There was no rash. Eye, ear, nose and throat examinations gave negative results except for moderate inflammation of the pharynx. The lungs were clear and the heart was normal. There was no lymphadenopathy. The liver was felt 2 cm below the right costal margin. The spleen was not palpable. There was a moderate degree of mental confusion and some increase in motor activity, and it was difficult to keep the patient in bed.

Examination of a blood smear on admission showed many parasites of the *Plasmodium falciparum* type. Blood studies showed 4,210,000 red blood cells per cubic millimeter, hemoglobin 90 per cent and 4,850 white blood cells per cubic millimeter. The differential count was 64 per cent polymorphonuclear leukocytes, 24 per cent lymphocytes and 12 per cent monocytes. Urinalysis was negative.

The patient was treated with atabrine dihydrochloride 1½ grains (0.1 Gm) three times a day by mouth for five days. A blood smear on October 17 was again positive for *Plasmodium falciparum*. No parasites were demonstrated in the blood after completion of the course of atabrine. The patient, however, continued to manifest abnormal behavior characterized by increased psychomotor activity, euphoria and slight confusion. He was given quinine 5 grains (0.3 Gm) three times a day for one week and two doses of plasmochin. By October 30 his mental state had improved somewhat but he complained of generalized malaise and weakness. He was discharged from the hospital to duty on November 8.

On return to his organization he again manifested abnormal behavior and was again referred to the hospital and admitted November 10. The patient complained chiefly of headache and vomiting. The oral temperature was 99.4 F, pulse rate 100 and respiratory rate 20.

On examination he was amenable and cooperative, lying quietly in bed. He was definitely tremulous, with a fairly constant coarse tremor of the extremities on the right side. The patient was unable to give an adequate or coherent story of the events which led up to his hospitalization, though he was oriented in all spheres. There was a decided memory defect, especially for recent events, and some of his replies were irrelevant. He did not recognize one of the physicians who had examined him a half an hour before. He expressed no ideas of reference, no hallucinations and showed no disturbance in affect. Neurologic examination elicited a Babinski sign on the right. The reflexes were slightly less active on the right than on the left side, and the abdominal reflexes on the right were slightly diminished. The red blood cell count was 4,360,000 per cubic millimeter, hemoglobin 90 per cent and the white blood cell count 11,400 with 54 per cent polymorphonuclear leukocytes, 36 per cent lymphocytes, 6 per cent eosinophils and 4 per cent monocytes. Urinalysis was negative. The Kahn reaction of the blood was negative. A blood smear was negative for malarial parasites.

The nature of the illness was not recognized immediately and malarial treatment was not instituted because he was unable to give an adequate history and because he was admitted to a section of the hospital different from the first admission. The following day he was still confused, neurologic signs persisted and the temperature was 102 F. A lumbar puncture was performed on November 12. Spinal fluid was clear and colorless and under normal pressure. There were 64 cells with 40 per cent polymorphonuclear leukocytes and 60 per cent lymphocytes. There was a heavy trace of globulin. Repeated blood smears for malarial parasites were negative. After several days of low grade fever without chills the temperature became normal.

On November 14 neurologic examination revealed a partial mixed aphasia, alexia and agraphia. He had extreme difficulty in expressing himself, in naming objects and in reading newspaper headlines and was unable to write his name correctly. There was still a definite memory defect for recent events. Babinski and Chaddock signs were elicited on the right and Oppenheim signs and forced grasp reflexes bilaterally, greater on the right than on the left. There was no papilledema or nuchal rigidity. On November 17 he appeared greatly improved. He was more alert and was able to read and write much better. A five day course of atabrine was given as before. On November 22 his mental condition had improved further. A Babinski sign was still present on the right side and the abdominal reflexes were depressed on the left. There was almost complete recovery from the alexia, agraphia and aphasia. On November 25 neurologic examination was negative except for diminished abdominal reflexes and delayed plantar flexion on the right side. He had, however, become definitely euphoric, overproductive and elated and showed a decided increase in his psychomotor activity. He made grandiose plans and was typically hypomanic. Slight difficulty in reading was still present and he would leave out occasional words in writing. By November 30, overactivity had increased to the point at which it became necessary to transfer the patient to the psychiatric ward. He was very distractible and euphoric and stated that he had never felt better in all his life.

A sample of writing addressed to his fiancée during this time is as follows: "Honey, never have I been so happy in all my life. Captain B is ready to see if we are still going to marry. You did not say one word about it, but honey, I already had another hemonion that I have been having. I have as much sense as anybody now. Boy that Captain B has been my very best friend in an hour of need. He and I have grown to be very close friends. We want to get that camera and take some of the scenery of all nurses and doctors. Since that night I told those nurses that I could not sleep I read an article in the paper on a man who never sleeps. He does nothing but sip his old tea. Don't try to force any man to sleep when a man has the fantastic ideals always and crased ideals of my time that would be one unfortunate moment alive."

In the psychiatric ward he showed gradual improvement. He became less talkative and his judgment improved. As the mental condition improved, he began to complain of malaise, ready fatigue, paresthesias on the left side of the body and pain in the lower extremities. Neurologic examination, however, was unrevealing. By December 26 his memory was good. The pain and paresthesias were less pronounced. He was quiet and cooperative and had developed insight into his mental upset. Improvement continued until Jan 10, 1942, when he was discharged from the hospital.

His family history and previous personal history were obtained through the assistance of the American Red Cross. The patient's grandparents had died of natural causes at advanced ages and there was no history of mental or nervous disorder in his parents and five siblings.

The patient's birth and early development were normal. He had completed one year of college. His attendance, study habits and behavior were considered perfectly normal. He had never manifested any mental abnormality and had suffered no serious injuries or disease, was not addicted to the use of alcohol and had been considered well adjusted.

COMMENT

The patient's illness began with symptoms which suggested influenza. A blood smear was done shortly after admission to the hospital because the ward officers considered the possibility of malaria. Symptoms of cerebral involvement were manifest almost from the beginning but did not command serious attention and consideration until the second hospital admission, when they dominated the clinical picture.

The fairly rapid response to specific therapy left little doubt concerning the nature of the illness. The manic psychosis which the patient developed is believed to have been secondary

to organic brain disease, especially in view of the completely negative past history of any mental disorder

It is generally accepted that estivoautumnal malaria is responsible for the major portion of deaths due to uncomplicated malaria and that fatal cases are usually associated with cerebral involvement¹. In cases in which there is cerebral localization of the parasites, the onset is usually rapid with delirium or coma, and death frequently ensues without a return to consciousness. This is commonly the course in drug addicts who become directly inoculated with infected blood. Many different types of atypical malaras with symptoms in the nervous system have been described. They have been classified as (1) meningitic type, (2) monoplegic or hemiplegic type, (3) myelitic type, (4) ataxic type (5) disseminated sclerotic type, (6) bulbar type, (7) cerebellar type, (8) cerebral type, (9) polynuritic type (10) Korsakoff type and (11) aphasic type.

The classification indicates that the disease may involve any part of the nervous system and resemble many different disease entities. The symptoms produced depend on the anatomic localization of the disease.

In fatal cases, the brain shows a gross brownish discoloration of the gray matter with macroscopic punctate hemorrhages into the white matter. Stained sections reveal the capillaries filled with parasites in various stages of development¹.

In the present case, observations indicate that the predominant involvement was in the frontal lobes. The picture is one of rather diffuse organic brain disease complicated by the development of an organic psychosis and terminating with recovery.

SUMMARY

A puzzling case of organic disease of the brain, manifested by aphasia, alexia, agraphia, memory defect and confusion associated with involvement of the pyramidal tracts and bilateral forced grasp reflexes and complicated by an organic psychosis proved to be one of cerebral malaria. Cure was effected by the early administration of atabrine.

TWO CLINICALLY USEFUL SIGNS

- 1 THE WHISTLE-SMILE REFLEX IN THE PARKINSONIAN SYNDROME
- 2 THE NEPHRITIC STARE IN CHRONIC GLOMERULONEPHRITIS

FREDERIC M. HANES, M.D.

Florence McAlister Professor of Medicine, Duke University School of Medicine
DURHAM, N. C.

1. When the normal individual is requested to whistle he does so and then smiles, probably as a mimetic response to the absurdity of unmotivated whistling. The patient suffering from the parkinsonian syndrome does not smile after whistling. For many years I have employed this simple test as an aid to rapid orientation and have found it to be very helpful and reliable.

2. While I was serving as a house officer at Johns Hopkins Hospital in 1909 a patient was admitted in a suburemic state, showing definite exophthalmos¹. Under treatment she improved and concomitantly the proptosis became less pronounced. After some months she was readmitted and died in uremia. An autopsy confirmed the clinical diagnosis of chronic glomerulonephritis. The thyroid was normal.

Thirty years experience with the eye signs of Bright's disease, which are similar in every way to those seen in toxic goiter, has proved that they are frequently useful in differentiating cardiac breakdowns as a result of chronic kidney disease from those due to other causes. Cardiac or cerebrovascular syndromes frequently mask the basic renal background in chronic glomerulonephritis, nephrosclerosis, necrotizing arteriolitis and pyelonephritis until the onset of renal decompensation.

The 'nephritic stare' does not serve to differentiate various types of nephritis. My assistant Dr. Joseph Stevens studied in this clinic 100 instances of chronic Bright's disease, with especial reference to eye signs. Forty-three of these showed the 'nephritic stare,' some with varying degrees of proptosis,

Fig. 1—The nephritic stare in a patient with chronic glomerulonephritis.

as measured by the ophthalmometer. Thirty of these patients came to autopsy, with the following anatomic diagnoses:

Chronic glomerulonephritis with 'nephritic stare' and proptosis 16

Fig. 2—Exophthalmos in a patient with chronic glomerulonephritis proved by autopsy.

Chronic glomerulonephritis with 'nephritic stare' and no proptosis 0

Arteriosclerotic nephritis with 'nephritic stare' and proptosis 7

² Hesperia, Milton. Malaria Among Drug Addicts in New York City. Pub. Health Rep. 49: 421 (March 30) 1934.

³ Castellani, Aldo and Chalmers, A. M. Manual of Tropical Medicine New York: William Wood & Co. 1919.

From the Department of Medicine, Duke University School of Medicine.

¹ Barker, L. F., and Hanes, F. M. Exophthalmos and Other Eye Signs in Chronic Nephritis. Am. J. Med. Sc. 135: 469, 1909.

Arteriosclerotic nephritis with "nephritic stare" and no proptosis 5

Pyelonephritis with "nephritic stare" and no proptosis 2

Negro patients 14, white patients 16

Although I have used the term "exophthalmos" it is more correct to refer to the sign as the "nephritic stare" (fig 1), for proptosis is as a rule, not measurably present, even when the fixed stare is clinically obvious. The stare is indistinguishable from that often seen in early toxic goiter from which, of course it must be differentiated. On the other hand Plummer and Wilder² are in error when they say that the clinical impression of proptosis in such patients is very seldom confirmed by exact measurements with the exophthalmometer. A measurable grade of exophthalmos is not rare (fig 2), though the 'nephritic stare' may be clearly discernible in the absence of proptosis.

The factor that leads to the characteristic appearance of the 'nephritic stare,' exclusive of actual proptosis, is retraction of the upper lid (Dalrymple's sign). This lid retraction may produce the appearance of exophthalmos when no proptosis is actually present.

Council on Industrial Health

THE COUNCIL ON INDUSTRIAL HEALTH HAS APPROVED PUBLICATION OF THE FOLLOWING SPECIAL WARNING BULLETIN ON EPIDEMIC KERATO CONJUNCTIVITIS

C. M. PETERSON, M.D., Secretary

EPIDEMIC KERATOCONJUNCTIVITIS

This report is issued jointly by the U. S. Public Health Service and the Committee on Industrial Ophthalmology of the Section on Ophthalmology, American Medical Association. It is recognized that relatively few cases of epidemic keratoconjunctivitis will be reported in areas which are not essentially industrial, but the condition has appeared so extensively throughout the country that the agencies sponsoring this report hope that physicians everywhere will be prepared to apply the recommendations listed below promptly and effectively.

INCUBATION PERIOD

The incubation period in epidemic keratoconjunctivitis ranges from five to ten days.

CLINICAL MANIFESTATIONS

The onset may be preceded by a low fever and mild generalized malaise. The local ocular symptoms are merely those of a foreign body or conjunctival irritation. One eye is usually affected first, and in a large percentage of cases the second eye becomes infected within five to eight days. Preauricular and submaxillary glandular involvement with tenderness is common in a high percentage of cases.

Edema of the lids and the conjunctiva, especially the transitional fold, is very frequent. The conjunctiva presents the appearance of a simple purulent conjunctivitis but with little or no formation of pus. Small areas of pseudomembrane are not infrequent and when removed leave either small white dotted points or some bleeding points. The bulbar conjunctiva becomes edematous early. At this stage there is some lacrimation and photophobia but real pain and blepharospasm do not appear until the cornea becomes involved.

The proportion of cases in which corneal involvement occurs varies from 50 per cent to 90 per cent. In six to twelve days after the conjunctivitis appears the cornea becomes involved by the appearance of discrete gray infiltrates that lie in and immediately under the epithelial layer of the cornea. They may be confined to the periphery of the cornea but in a large percentage of cases involve the pupillary area of the cornea directly. These infiltrates are discrete and seldom become complicated by an erosion of the corneal epithelium with

resultant staining with fluorescein. The extent of visual impairment depends on the number of infiltrates and their location.

CLINICAL COURSE

The disease is self limited. In the majority of instances the conjunctivitis disappears spontaneously in fourteen to eighteen days. The corneal complication may disappear in seven days or may last for many months. The longer they persist the greater is the danger of permanent visual impairment.

LABORATORY FINDINGS

Scrapings of the conjunctiva show a preponderance of monocytes. Cultures and smears either are negative or show the usual contaminations.

TREATMENT

There is no specific treatment that has shown a definite influence on the course of the disease. During the acute stage the eyes should be kept clean with irrigations of boric acid isotonic solution of sodium chloride or 1:5000 mercuric oxy-cyanide. If there is much photophobia 1 per cent holocaine may be instilled at frequent intervals. Five per cent sulfathiazole ointment has been used as has 5 per cent solution of sodium sulfathiazole sesquihydrate. For persistent corneal infiltrates, the X-rays have seemingly yielded some results.

PERIOD OF INFECTIVITY

It is not yet known how long the danger of transmission to others exists. At present for practical purposes a sufferer from epidemic keratoconjunctivitis may be allowed to return to work when the active conjunctivitis has disappeared.

PREVENTIVE MEASURES

At present the only preventive measure known is complete isolation of infected persons. As the disease has been transmitted through medical personnel the most meticulous asepsis must be insisted on. Not only must physicians and nurses wash their hands thoroughly with soap and water after each patient, but also eye droppers, solutions and instruments must be sterilized to prevent infection of noncontaminated persons. The infected individual must be told of the danger of transmission of this disease to others not only in the plant, but even in the home surroundings. It is suggested that in industrial plants where epidemic keratoconjunctivitis has made its appearance the following methods of procedure be adopted:

1. In smaller plants with a limited personnel every individual with a red eye should be stopped at the entrance of the plant and sent direct to the plant physician to determine whether or not epidemic keratoconjunctivitis is present. In larger plants where such a procedure is not possible supervisors and foremen should be instructed in detail to make rounds immediately when a fresh shift starts and send any individual with a red eye to the medical office.

2. If the cases are to be treated at the medical department of the plant a separate room should be set aside for such cases and in that room there must be exercised the most scrupulous asepsis even to washing the arms of the chairs in which the patients sit. Aside from the aseptic and separate care of the recognized cases of the disease, special cleanliness of the hands of the physician in the general clinic should be maintained with the use of an effective disinfectant between cases lest the infection be spread by means of undiagnosed cases, especially those suspected of having foreign bodies in the eye.

3. Every case of epidemic keratoconjunctivitis should be excluded from the communal facilities of the plant until the inflammation has subsided to the point where the plant physician considers it no longer transmissible.

4. Explicit instructions should be given to every individual regarding the danger of transmission and emphasizing the decrease in the war effort as a result of the time lost from epidemic keratoconjunctivitis.

5. The local health authorities should be notified immediately of the existence of individual cases.

SATURDAY, APRIL 3, 1943

NEUROPSYCHIATRY IN THE ARMY

Under Medicine and the War in this week's issue of THE JOURNAL appears a brief report of the establishment of a special school for neuropsychiatry under the auspices of the United States Army Medical Corps. Psychiatric problems represent today some of the most important of those that confront our armed forces. In 1918 there were 7 men of each thousand discharged for psychiatric reasons, whereas in 1942 the rate was 4 per thousand. At the time of induction in 1918 only 20 men of each thousand were discharged for psychiatric reasons, now about 75 of each thousand are rejected for such causes. This does not mean that more men are now mentally unfit, our scientific methods have improved sufficiently in the interval to enable more accurate detection of such cases. The indications are that 30 per cent of the casualties now arriving from the war zones are psychiatric in character or have some well defined psychiatric aspects. Nervous and mental disorders are major causes of medical discharge from the Army. Conceivably the technic developed for induction, including the filtering by the local draft boards and the induction boards, has not been sufficient to prevent entrance into the service of a large number of unstable persons. The service in this respect is improving, but, unless the deficiencies are fully recognized, those who are striving for this improvement may be handicapped and delayed in accomplishing a satisfactory result.

The detection of the mentally unsuited or the potential psychiatric casualty at induction is one of the most important tasks of military neuropsychiatry. The lack of sufficiently trained examiners, the lack of technic for securing necessary historical information about inductees, the large numbers inducted and the short period of time during which induction occurred are all contributory factors in the failure to control properly the admission of those not mentally qualified. The fault cannot be credited to any single agency. Every-

thing possible was done by Selective Service headquarters and by cooperative efforts between the armed forces and Selective Service. No doubt the training of many more men in the special problems of psychiatry related to the armed forces will help this situation.

The need for special consideration of neuropsychiatric problems was recognized early after our entrance into the war with the establishment of a committee for this purpose in the Division of Medical Sciences of the National Research Council. In February 1942 a Neuropsychiatry Branch was established in the Surgeon General's Office under Lieut. Col. Patrick S. Madigan, who had many years of experience in this specialty in the Regular Army. As the problem grew and became more definitely recognized an assistant chief, Lieut. Col. Malcolm J. Farrell, was appointed in April 1942. Then in August 1942 Col. Roy D. Halloran was assigned to duty as chief of this branch. Among the most important duties of the branch are (1) giving advice to the Surgeon General and other governmental agencies on neuropsychiatric matters, (2) recommending policies for the Army in neuropsychiatric matters, (3) inspecting neuropsychiatric facilities in hospitals and clinics, (4) making recommendations for circular letters and directives regarding neuropsychiatric matters, (5) reviewing neuropsychiatric information coming into this office, (6) maintaining a card index of location and qualifications of neuropsychiatric officers, (7) consulting with the personnel division and recommending assignments and transfers of neuropsychiatric officers, (8) reviewing and approving scientific publications submitted by neuropsychiatric officers and (9) attending and participating in National Research Council meetings.

As this section of the Surgeon General's Office became oriented in its responsibilities, consultants were appointed to coordinate and supervise clinical and administrative neuropsychiatry. Thus far four consultants have been appointed: Lieut. Col. Franklin G. Ebrugh, M. C., to the eighth service command, Lieut. Col. William C. Meisinger, M. C., to the fourth, Major Garland H. Pace, M. C., to the seventh and Lieut. Col. Douglas A. Thom, M. C., to the second. In the European theater of operations Lieut. Col. Lloyd J. Thompson acts as consultant in neuropsychiatry and in the Southwest Pacific theater of operations Lieut. Col. Samuel A. Chalmers.

Most important in this service has been the establishment of the School of Military Neuropsychiatry, which has already been mentioned. More than a hundred and twenty officers have already been trained in this course. A neuropsychiatric unit at the Thirty-Sixth Station Hospital has been organized under the command of Lieut. Col. Ernest H. Parsons. This unit is functioning as a neuropsychiatric center in the European theater.

and is providing indoctrination instruction for newly arrived neuropsychiatric officers so that they may familiarize themselves quickly with the problems and case material. Especially qualified trained psychiatrists have been assigned to carry out planned mental hygiene programs at replacement training centers.

The question of morale is being met by liaison established between the Neuropsychiatric Branch, represented by Lieut. John Appel, and the Special Services Branch of the Army, which is under the direction of Gen. Fred Osborn.

Finally, neuropsychiatry in the armed forces must be especially concerned with problems of delinquency. The crude methods of the past have given way to more humane and satisfactory handling of the problems of the homosexual. No longer is it necessary to subject cases that are so definitely in the medical field to the routine of military court martial.

The development of the Neuropsychiatric Branch of the United States Army Medical Department represents one of the most important achievements in the advancement of military medical science. All of those officially responsible merit commendation for their cooperation in the significant results that have already been secured.

EXTENSION OF PUBLIC HEALTH COVERAGE TO THE NATION

Forty million of our people live in communities or in areas in which there is no access to the full time services of a professionally trained medical officer of health and the associated sanitarians and public health nurses of a local health department of civil government. On June 10, 1942 the House of Delegates of the American Medical Association unanimously voted its approval of extension of such services. Now the Committee on Administrative Practice, one of the standing committees of the American Public Health Association, has offered a plan to improve the situation.

Tax supported public health services have been distributed unevenly and not in all respects in relation to sanitary needs or in proportion to the population units of local government. In fact, there are conditions of local government, cities, townships and counties, in which duplicating and to some extent conflicting health services are provided because of local rivalries of a political nature. State laws in some instances do not authorize cooperative arrangements for a single health officer for adjacent communities or counties. Good health service for prevention of communicable, occupational, nutritional and other preventable diseases, and for the protection of the health of mothers and children, cannot be achieved for a state solely or effectively or economically by a state department of health unless the counties and cities are sufficiently concerned with

local health conditions to support their own community health services. By the same token federal programs for a higher level of national health fail in effectiveness for lack of facilities of local government through which federal grants can be used by agreement with the state.

In July 1942 some 62 million people living in the continental United States were provided by local governments with full time medically officered health protection. In addition 16½ million persons were served by county or district health departments operated by a state department of health, and about 12 million more people living in cities with full time health services. There remain 41,052,600 persons, or 31 per cent of our population, in 1,687 counties in 41 states for whom no full time health service is provided by either local or state government.

The committee of the American Public Health Association presents a half dozen basic principles of health administration and suggests that not more than 1,127 units of local health jurisdiction are needed for the total coverage of the continental United States. The units are, of course, in addition to the respective state departments of health and the health services of the various bureaus and departments of the federal government. It is to be assumed that a city and the county within which it is located shall have a single headed health service. It is suggested that a unit of less than 50,000 population can rarely maintain an efficient tax supported local health service and that counties with small populations should be authorized by state law to combine with adjacent counties to support and be served by a single district or multicounty health department.

Among the 3,070 counties of our states there are many with populations so small and economic resources so slender as to preclude the possibility of supporting even the minimum personnel and functions of a local health department. The basic public health law of each state should not only permit but specifically authorize the creation of local health units of population size and area compatible with efficient and economical public service. The law should provide furthermore for the selection of professional personnel on a sound civil service or merit system and authorize the levying of taxes to support the health services.

The American Public Health Association, through its Subcommittee on State Health Administration, has recently completed a study of state health administration in Illinois, undertaken at the request of the state director of public health with the approval of the governor. A summarized report of this study discloses a recommendation that legislation be enacted to permit the establishment of full time county or combination of county health departments. Following a distribution of this report, the Research Department of the Illinois Legislative Council made available a factual study of

county health departments in the state for use by the general assembly in considering any legislation that might be proposed. Now a bill has been introduced by Senator Searcy, as S 244, authorizing the establishment and maintenance of county and multiple county health departments in the state.

Permissive in form, this legislation proposes that county full time health departments may be created either by resolution of a county board or by the voters of a county and that multiple county health departments may be set up. If four or more counties wish to associate themselves in establishing and maintaining such a department, prior approval must be obtained from the state department of public health. Provision is made for the levying of a special tax not to exceed 1 mill on the dollar on all taxable property in the county or counties involved to finance the operation of the department. Existing full time health departments in cities, villages or public health districts with less than 500,000 inhabitants may be retained or they may be abandoned and become integrated in the county or multiple county health department. Health departments in communities with a population of 500,000 or over will apparently not be affected by the bill. Each county health department will be managed by a board of health appointed by the president or chairman of the county board. At least two members must be physicians licensed in Illinois to practice the healing art in all its branches and at least one member must be a dentist licensed in Illinois. All members must be chosen for their special fitness for membership on the board. Multiple health departments are to be managed by a board of health consisting of three members appointed from each county by the president or chairman of the county board.

Provision is made for the appointment of medical, dental and nonmedical advisory committees and for the appointment, for each department, of a chief medical officer to act as executive officer, and of such other officers and employees as may be approved by the executive officer, all appointees to meet the qualifications prescribed by the Illinois State Civil Service Commission. The functions to be exercised by the departments are set forth in broad groupings, including the right to pass such rules as may be necessary for the improvement and protection of the public health. The people of Illinois may well reflect on the importance of this proposal, establishing as it does a framework on which may be constructed a comprehensive public health program to function in the interest of the health of all the people of the state. Legislation with a similar objective, although differing in detail and approach, was proposed this year in the states of Arkansas, Georgia, North Dakota, Utah, Washington and Wyoming.

Each state medical society may with advantage avail itself of the detailed information in the hands of the American Public Health Association and analyze its own situation in conference with its own state health officer. Permissive or enabling legislation to provide for local health units and their support should be supported by the professional influence of the physicians of the state, unless existing laws are adequate.

The career of public health as a specialty of medicine requiring graduate university training and practical experience is so far accepted as part of the pattern of preventive medicine that the survival of the part time general practitioner as the local administrator of a health department cannot be encouraged by the medical profession or be recommended to the taxpayer as the best his money can buy in public health.

FOOD POISONING

During the present mobilization the incidence of food poisoning in U S Army troops is much less than that being experienced by other armed forces engaged in the present conflict. However, many food poisoning outbreaks are due to (1) carelessness in the handling of sanitation involved in the processing or serving of food and (2) the presence of unrecognized human carriers of enteric pathogens in the permanent food handler group.

The Army has focused the attention of medical officers and personnel involved in the operation of all messes on the necessity of protecting food adequately from contamination by processing and serving under sanitary conditions and by preventing undue retention of food that may be potentially contaminated prior to its being served. Laboratory facilities have been made available for the investigation of these outbreaks when they occur, and every effort is being made to determine their source.

In general food as delivered by the manufacturer or wholesaler for processing in army kitchens has not been found to be an important factor in the cause of these outbreaks. Most of the outbreaks that have occurred have been due to the fact that foods such as potato salad, ground meat and sliced ham have been processed too long in advance of serving or have been stored under conditions favoring bacterial growth. Those outbreaks that have not been satisfactorily worked out with regard to the cause and the source of infection have in many instances been due to the fact that personnel involved have been convinced that physical factors or bacteria such as the staphylococcus were the only agents involved in the outbreak. Staphylococcus food poisoning does occur, and this type of infection is important as an etiologic agent of food poisoning. However, when mediocre bacteriology is done in con-

nection with the investigation of the outbreaks the individuals conducting the investigation usually isolate a coccus which by gross methods of examination is identified as a staphylococcus. This finding, in conjunction with perfunctory examination for the *Shigella* and *Salmonella* organisms, leads to the conclusion that the outbreak is essentially staphylococcal in origin. These conclusions are not justified in many instances. The findings of more thorough examinations definitely proved that the outbreak itself was not due to staphylococci but to *Shigella* or *Salmonella*.

The detection of permanent food handling carriers of *Shigella* or *Salmonella* and their removal from this type of work definitely limit the possibilities of subsequent outbreaks. If the examination of the outbreak is perfunctory and staphylococci are blamed for the outbreak without adequate investigation for other possible organisms, corrective action will not be taken and the outbreaks will continue to occur. Medical schools and other scientific organizations should bring to the attention of physicians the necessity for insisting on thorough investigations of food poisoning outbreaks and not accept perfunctory explanations with regard to their cause.

Current Comment

INVALID DIETS AND FOOD RATIONING

Physicians who are especially concerned with diets for invalids should note that ration order 13, issued by the Office of Price Administration under date of Feb. 9, 1943, covering all canned, dried and frozen fruits and vegetables, permits under article II, section 25, extra rations for invalids. The order reads:

Consumers who need more processed foods because of illness may apply for more points. (a) Any consumer whose health requires that he have more processed foods than he can get with War Ration Book Two may apply for additional points. The application must be made, on OPA Form R-315, by the consumer himself or by some one acting for him and may be made in person or by mail. The application can be made only to the board for the place where the consumer lives. He must submit with his application a written statement of a licensed or registered physician or surgeon showing why he must have more processed foods, the amounts and types he needs during the next two months and why he cannot use unrationed foods instead.

(b) If the board finds that his health depends on his getting more processed foods and that he cannot use or cannot get unrationed foods, it shall issue to him one or more certificates for the number of points necessary to get the additional processed foods he needs during the next two months.

The application form referred to OPA Form R-315, is apt to be somewhat confusing to patients. It is titled "Sugar Special Purpose Application" and was developed primarily to meet the need for home canning. It is being used temporarily, until a more adequate form can be developed. The procedure indicated in section 25 may be changed somewhat in the future in which case due notice is to be provided.

THERAPY OF SEVERE BURNS

Generally it is believed that severely burned patients should be kept warm because of the fall in body temperature commonly accompanying shock. This conventional belief is now challenged by Elman and his co-workers¹ of the Department of Surgery, Washington University School of Medicine, St. Louis as a result of their study of the effects of different environmental temperatures on the mortality rate of severely burned laboratory animals. In the course of a study of chemical changes following severe burns, the St. Louis surgeons noted an increased mortality of their experimental animals during several hot days of the summer when the environmental temperature rose to 95 F. The suggested deleterious effect of such high temperatures was tested on groups of rats placed after burning in rooms at different constant temperatures. Summarizing their experimental data, Elman concludes that the least mortality occurs at an environmental temperature of 75 F, increasing to a 100 per cent mortality with either an increase or a decrease of 20 degrees F from that therapeutic optimum. Their most favorable temperature (75 F) is but slightly higher than the level accorded to be the normal average for human comfort. The St. Louis surgeons conclude that "the commonly used heat tent which increases the environmental temperature above that point will be deleterious by increasing the mortality in severe burns" and that the room temperature should be lowered for burned patients in climatic extremes where the environmental temperature rises much above 75 F.

TETANUS IN THE MIDDLE EAST

In the British army each man is inoculated with two doses of 1 cc of tetanus toxoid at an interval of six weeks. A "boosting" third dose is given not earlier than six months later. Although the procedure is voluntary, probably over 95 per cent of the soldiers, according to Boyd and MacLennan,¹ are inoculated. Only recently have a large percentage received the third dose. Each wounded man is given a dose of 3,000 international units of tetanus antitoxin. Further weekly doses of the antitoxin are given to the patients who have not been actively immunized. Despite the relative rarity of tetanus bacilli in soil samples of the Middle East (88 per cent of ninety-one samples of earth collected between Daba and Benghazi) the organisms are not uncommonly found in wounds. In a series of 214 wounds of a severe type, *Clostridium tetani* was found in 18 (8.4 per cent). During the first two years of war in the Middle East 18 cases of tetanus were reported in the fighting forces. Of these 13 were in the nonimmunized group, while 5 occurred among the actively immunized. The former group had six fatalities and the latter three. From these figures active immunization, while effective in preventive tetanus, apparently has definite limitations. The authors emphasize that 1 of the 3 who died did not have his third dose, while the other 2 in all probability succumbed to an overwhelming infection resulting from masses of

¹ Elman, Robert, Cox, W. V., Jr., Lischer, C. E. and Mueller, A. J. *Proc. Soc. Exper. Biol. & Med.* 51: 350 (Dec.) 1942.
¹ Boyd, J. S. K. and MacLennan, J. D. *Tetanus in the Middle East. Effects of Active Immunization.* *Lancet* 2: 745 (Dec. 26) 1942.

necrotic tissue in their wounds. Boyd and MacLennan stress therefore the necessity of careful surgical treatment with removal of all dead tissue as an important factor in preventing the development of tetanus. The importance of the third, the "boosting," dose of the toxoid, because of its augmenting effect on antitoxin production, is generally accepted.

THE SUPPLY OF PHYSICIANS

Elsewhere in this issue (p. 1160) appears a report released by the Office of War Information concerning the supply of physicians in the United States at this time. Significant is the opinion of the governmental agency that the health of the nation as a whole has not been seriously impaired by any shortage of doctors, that the number of communities critically in need of doctors is not great compared with the total number of communities in the country, and that it might have been better if there had been from the first an agency capable of protecting the needs of the civilian population in the recruitment of doctors. Thus far the relocation of physicians has not wholly solved the problems that prevail. The situation is not now out of control, but luxury medicine is out for the duration. Evidence is not available as to the nature of the personnel utilized by the Office of War Information in making this survey or as to the technique used by the surveyors in securing information. Apparently the investigators failed to utilize fully the facts and data of the Procurement and Assignment Service. For example, the figures of percentage attainment of quotas on Dec. 1, 1942, are at variance with those tabulated by the Procurement and Assignment Service from the Adjutant General of the U. S. Army and the Surgeon General of the U. S. Navy. Frequently throughout the release, isolated or remote communities are cited with low physician population ratios and given as evidence of the breakdown of Procurement and Assignment Service. Upon closer inspection it becomes evident that many of these communities did not have more favorable ratios prior to the war. Rather too great emphasis seems to have been placed on a statement from one county medical society in a Southern state which was certainly not typical of the vast majority of medical societies in this country. Moreover, the investigators seem to have been a little naive in accepting such statements as that of the physician who is said to have slept only three hours a night for a considerable period. The report will, of course, come to the attention of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians, which is the governmental agency charged with the problem of supplying physicians for the armed forces, industry and the civilian population. As a branch of the War Manpower Commission, with which also is associated the Selective Service System, there seems to be no reason why this agency should not be able to meet needs as they develop, keeping in mind always, however, the fact that the first problem of the nation is the winning of the war and that it is the duty of civilians in wartime to sacrifice largely in maintaining the armed forces at the utmost peak of health and physical fitness.

THE INCREASING INCIDENCE OF BACILLARY DYSENTERY

Recently Silverman and Friedrichs¹ reported a study of some 700 bacteriologically proved cases of bacillary dysentery or *Bacterium dysenteriae* infection of the bowel. The latter term is reserved by the authors for cases of chronic infection with the bacillus of dysentery in the absence of diarrhea or the classic syndrome of dysentery. The responsible organism in the cases of dysentery observed by Silverman in a previous report was *Bacterium flexneri*. At a later period the predominant organism was found to be the lactose fermenter of Duval. At present the cases show increased virulence and more frequent incidence of complications, the predominant strains being those of *Bacterium shigae* and of *B. flexneri*. Although these observations are confined to the New Orleans area the disease shows a definite tendency, as predicted by Silverman in an earlier report (1926), to become endemic in many states of the Union. This prophecy has been borne out by the reports of cases from the states of New York, New Jersey, Illinois, California, Vermont, Missouri and Virginia. The authors advance the concept that arthritis, myocarditis, vascular dysfunction and even obstructing spasm of the colon as seen in chronic dysentery are probably manifestations of protein hypersensitivity to the bacillary dysentery infecting the patient. Silverman treats such manifestations as allergy by desensitization of the patient with autogenous vaccine. It has not been generally appreciated that these infections may cause deeply penetrating lesions in the bowel with consequent perforation. A person with bacillary dysentery infection of the bowel in a period of remission, following treatment or without treatment, is always a potential victim of this most serious complication. The problem posed by the increase in incidence of bacillary dysentery is pertinent to the aggregation of great numbers of men in the different camps and various communities. The authors believe that the possibility of the spread of this infection from a local community to one of the camps is great. Close vigilance should be observed, should dysentery appear, the patient should be isolated and every effort be made to prevent the spread of the disease.

NEW JOURNAL OF GASTROENTEROLOGY

The council and members of the American Gastroenterological Association have felt the need of a journal with editorial and advertising policies directly under their control. The first issue of the new journal under these auspices, entitled *Gastroenterology*,¹ has now appeared. It contains articles by a number of specialists in the field of gastroenterology. A further list of interesting articles is scheduled for appearance in later issues. As pointed out by Dr. W. C. Alvarez, the editor, the success of the journal now will depend on the degree of interest shown in it by those physicians who are concerned with the advancement of gastroenterology.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

SCHOOL OF MILITARY NEURO-PSYCHIATRY

COLONEL ROY D HALLORAN

Medical Corps, Army of the United States
AND

LIEUT COL MALCOLM J FARRELL

Medical Corps, Army of the United States

The Neuropsychiatric Branch of the Surgeon General's Office announces the opening of a School of Military Neuropsychiatry at the Lawson General Hospital Atlanta, Ga. The clinical and administrative practice of military neuropsychiatry presents many new and difficult problems to the newly commissioned neuropsychiatrist. The civilian professional experience of neuropsychiatrists varies considerably: psychoanalysts, neurologists, state hospitals, prison psychiatry, child guidance and similar specialties. On entering the Army they are faced with common problems such as the selection and detection of mental misfits, the necessity for short periods of observation, puzzling and bizarre clinical manifestations peculiar to the military service and the administrative machinery set up to provide for the disposition of neuropsychiatric cases. It has been necessary, therefore, to provide some means whereby the practice of neuropsychiatry in the Army could be made more standard and uniform, to provide the individual officer with an opportunity to review subjects which he did not require in civilian life and to introduce him to the various administrative procedures which will bewilder him if no assistance is provided.

In recognition of these difficulties and to prepare the officer better for the handling of combat casualties, the School of Military Neuropsychiatry, which is unique in Army history and has already gained international attention, was developed with the active interest and support of Major Gen James C Magee, the Surgeon General, and Brig Gen Charles C Hillman, Chief Professional Services, Office of the Surgeon General, to provide practical instruction for already trained and qualified specialists.

Brig Gen William C Sheep, the commanding general of Lawson General Hospital, a well known military neuropsychiatrist, is commandant; the assistant commandant is Col William C Porter, also a prominent military neuropsychiatrist, who is in direct charge of the school. Colonel Porter teaches the military aspects of neuropsychiatry, based on his broad experience. Dynamic psychiatry, from a military point of view, is taught by Lieut Col M Ralph Kaufman and psychiatry from an organic point of view is taught by Major Joseph L Fetterman. Neurology is taught by Major William H Everts. Lectures on other related subjects are given by specially selected officers, while certain members of the class relate special experiences such as neuropsychiatry in the Air Corps Tank Destroyer, Ranger and other special training camps. While these subjects are covered by some didactic lectures, much time is devoted to seminars and round table conferences. Clinical material of a type obtainable only in Army hospitals is provided, since experience has shown that the best method of teaching military neuropsychiatry is by constant reference to and the use of military casualties. In this manner the military administrative considerations which have presented or may present difficulties are thoroughly discussed. Thus the various aspects of military

neuropsychiatry which confront the new officer and present difficulties to the older officers are well coordinated by excellent and experienced teachers. The advantages of mutual exchanges of experiences and opinions in the interest of uniformity and professional progress cannot be overestimated.

The quota of officers selected for each intensive four weeks' course, which began Jan 2 1943, include officers from each service command and the Air Corps together with newly commissioned officers from training pools in general hospitals. In this manner new officers have the advantage of the experience of older officers and the older officers have in turn the opportunity of evaluating their experiences and methods in the light of experiences and methods of others. Here is demonstrated the adaptation of clinical teaching the bedside method to the field of military neuropsychiatry.

PSYCHIATRIC OUTPATIENT DEPARTMENT AT MITCHEL FIELD

The 'outpatient department of psychiatry at Mitchel Field N Y, where soldiers with emotional and mental problems may receive advice and treatment without hospitalization was established five months ago. Among 100 soldiers who have consulted the medical officers many have been helped to make the transition from civilian to military life and to ease over emotional barriers that might have become serious. The chief of the Neuropsychiatric Service at Mitchel Field is Major Benjamin H Balser who directs the outpatient department in addition to the regular ward for mental cases both under the general supervision of Lieut Col Oliver K Niess, surgeon of Mitchel Field. On the neuropsychiatric staff are First Lieut William L Fearing of the Medical Corps and Second Lieut Margaret L E Kram of the Army Nurse Corps. All the officers have had extensive training and experience in neurology and psychiatry. The provost marshal refers certain soldier prisoners to the clinic taking into account the possibility of mental illness as a basis for misbehavior, and seeks a recommendation from the psychiatrist. In many cases the punishment will be qualified accordingly. The psychiatrist is frequently called on to testify at courts martial involving such prisoners.

MEDICAL OFFICERS PROMOTED TO BRIGADIER GENERALS

In an announcement sent from the White House on March 25 it is stated that the President recommended to the Senate the promotion of the following medical officers from the rank of colonel to brigadier general (temporary):

Col George F Lull now in charge of personnel in the Office of the Surgeon General
Col James S Simmons epidemiologist
Col Norman T Kirk commanding officer of the Percy Jones General Hospital Battle Creek Mich
Col Leon A Fox recently assigned to the special commission on typhus fever

Brig Gen Norman T Kirk, commanding officer of the Percy Jones General Hospital, Battle Creek Mich, has been designated by the Surgeon General as chief consultant in orthopedic surgery. This is in addition to his duties as commanding officer of the Percy Jones General Hospital. In his service as consultant he will not be dislocated from his present station.

OFFICE OF WAR INFORMATION

THE SUPPLY OF PHYSICIANS

An Official Release from the Office of War Information

Approximately one third of the doctors in active full time practice in the United States have now been called to the colors. The Office of War Information has just completed a survey to determine the effect on the civilian population of this extensive depletion of the number of physicians and surgeons in private practice.

Between 40,000 and 45,000 doctors have entered the armed services. As the size of the Army and Navy increases, more will be called. The men in the uniform of the United States have been and will continue to be the best cared for medically in the world. But in total war the health and working power of the civilian is as important as the health and striking power of the fighter. The available supply of doctors must be fairly apportioned between them. The Office of War Information made its survey in some sixty communities in twenty states where shortages of doctors have been reported.

OWI representatives traveled through the South the Midwest the West the Eastern Seaboard—in three distinct types of communities: farming regions, where health problems existing for years have been intensified by war; small, quiet, towns that have mushroomed overnight into close packed centers around war industry and military encampments; large cities where ordinary congestion has been aggravated by war activity.

CONCLUSIONS

From first hand operation from the examination of authentic figures from protracted inquiries in these communities the following conclusions emerge:

1 Although there are areas critically in need of doctors because of withdrawals for the armed forces—a need frequently increased by expansion of population for war industry—so far the health of the nation as a whole has not been seriously impaired by the doctor shortage. Doctors these days are not only working overtime, they are—most of them—working practically all the time and in total disregard of their own health.

2 The number of communities critically in need of doctors is not great compared with the total number of communities in the United States. Those in need are, however, among those most vital to our war program.

3 In too many cases physicians were recruited for the armed services without sufficient regard for the welfare of the civilian population. There are, however, enough doctors remaining in private practice to give adequate care to the civilian population, provided they can be properly distributed numerically and according to special abilities.

4 The voluntary relocation of physicians from communities where there is an abundance of doctors to areas in acute need of doctors has proved extremely difficult and has not resulted in a solution to the problem.

5 In some communities local medical groups have resisted attempts to relocate outside doctors in their locality.

6 The situation as a whole is not now out of control but unless remedial steps are taken soon it will grow progressively worse. More physicians will be recruited for the armed forces and doctors in critical areas—many of them elderly—may succumb to exhaustion from overwork.

7 Luxury medicine, to which some Americans have become accustomed, is out for the duration. We can no longer afford to call doctors for imaginary ailments, and we must make the best and most efficient use of the medical facilities we have.

8 Medical shortages are not due in all cases to the war, although frequently the war has intensified them. For instance, many rural areas have never had a sufficient number of doctors. It is not the purpose of this report to recommend that long-standing problems be solved in time of war except as they relate to our progress toward victory.

PLACES VISITED BY OWI REPRESENTATIVES

One of our American traits is "doing the best we can with what we have." This is exemplified in a number of communities visited by OWI representatives. Faced with the possibility of

getting along with too few physicians or with none at all, these communities initiated classes in home nursing, they established health centers presided over by trained nurses, they taught infant care to mothers, they encouraged health building activities, through the local chapters of the Red Cross, nurses were supplied when doctors were not available.

One of the first places visited by OWI representatives was on the outskirts of a great aircraft plant near a large Atlantic seaboard city. Originally this community was a small country village about 12 miles from the center of the city. When the aircraft company went into war production, the whole area became a hive of hurrying humanity. As the village itself could not expand to meet the housing shortage, four trailer sites, with 1,500 trailers housing some 5,000 persons, were established. Many of these trailers are homelike, with tiny gardens and fences around them. There is also a housing project, which is being rapidly opened up. The total population for the area is approximately 25,000 and is increasing daily. The natural result of this mushrooming was a doctor shortage particularly of general practitioners and obstetricians. Something had to be done to provide medical care for these thousands of war workers and their families, in the trailer camps living conditions were especially precarious. A committee consisting of nearby doctors and the county health officer was organized to recommend ways of relieving the situation. There were six doctors living within the immediate area. Four left but were replaced. The committee arranged for nine others nearby to be on call. For three of these it meant setting up new offices in the district. There are, therefore, fifteen doctors now available, all of whom do obstetric work. If it is possible women about to have children are sent to their home communities. If this is not feasible they are delivered in the trailer, or, if the case is complicated they are taken to a hospital in the neighboring city. A specialist in obstetrics has recently opened an office in the area and takes cases on a consulting basis when they are referred to him by the local doctors. A trailer has been fitted up by the local doctors at their own expense to serve as a general office. This has some surgical equipment and each doctor has office hours one day a week. The telephone numbers of all fifteen doctors—the six in the area and the nine from nearby—are posted in all the outdoor telephone booths of the trailer camp and in the project manager's office.

One of the difficulties in this section is that of persuading the people—many of whom come from sparsely settled rural areas—to seek medical care when they need it. Some of them have a distrust of doctors. A public health nurse has been assigned full time to the trailer camps, and one of her jobs is to try to overcome this prejudice. She also does follow up work for the doctors, checking to see that directions are being carried out, giving advice on child feeding and care, arranging for x-ray examinations and in general being a mother confessor for the family. Many problems of this community still remain to be solved. Postpartum care is one of them. But at least effort has been made to coordinate medical facilities as effectively as possible.

There are many regions where conditions have not been improved. The OWI found sections where there was only one doctor to 5,000 or 6,000 persons with people frankly apprehensive over what might happen if any number of them became ill at the same time. They found doctors literally working themselves sick attempting to care for the scores of new patients brought to them by a swollen war industry area. They found places—such as a huge bomber plant on the outskirts of a large Middle Eastern city—where the thousands of persons living in trailers have no sewerage system, where sanitary facilities are inadequate and where there is a possibility of drinking water contamination. They found areas where reports by authorities as to the adequacy of medical care and the number of doctors available were completely misleading. One community near the Canadian border—present population 24,000, an important shipping center and adjacent to an Army encampment and several airfields—was reported as having eighteen doctors. Actually but six of these are effective, the others being too ill or too old to continue full time duty. The only surgeon in the community was recently commissioned for service in the Navy. All the

obstetric work is being done by one young doctor crippled by arthritis and heart trouble, who lately had cataracts removed from both eyes. Despite these ailments he is carrying on to the extent that he is actually endangering his life.

In another county on the West Coast, near a navy yard there has been an increase in population from 44,400 in 1940 to 110,000, and during 1943 it is expected that 25,000 more persons will move into this area. The present ratio of doctors is one to 4,000, not including the Navy personnel, who are cared for by Navy physicians. The hospital situation is critical revolving around antiquated equipment, one hospital having 108 beds and another, a private hospital, 18. The larger hospital is selecting some cases for treatment and turning away others equally in need of care. Hospitals in neighboring cities are high priced, crowded and reached by a long ferry or automobile ride. There are eight hundred trailers in this area. People living in them are having a difficult time keeping warm and protecting themselves against insanitary conditions. There are also housing projects where 6,000 people live, eventually 7,500 more people will live there in new projects. But regulations limit occupancy to war workers, and there are many workers essential to the community—such as bus drivers, grocers and policemen—who are not eligible for the project houses. Many among the several thousand women employees of the nearby navy yard, unaccustomed to performing manual work, have developed ailments which, although in most cases minor, demand treatment. Yet Navy doctors and the Navy hospitals are authorized to extend routine medical care only to male industrial casualties; women are treated only in emergencies. In all other cases they are expected to find their own doctor and go to the local hospital.

In one large Middle Western city it was found that a serious situation was relieved by the success of the county medical society in persuading outside doctors to come there. The site of important war plants with consequent increase in population, the city in some sections has a ratio of only one doctor to 5,000 persons, although the total ratio is one to 1,170. The county medical society journal carried appeals to physicians to settle in this city, with the result that four already have done so and two more are arriving in the near future. Two doctors who were recruited by the Army have been allowed to return to private life and their resumption of practice will further help the situation.

RELOCATION

Relocation of doctors to areas in need is never a simple procedure. Rural areas where there were too few doctors before the war were usually in low income sections which had never been able to support a doctor properly. Physicians are not willing, for the most part, to leave lucrative practices to move to such areas, the difficulty of finding modern housing for their families frequently adds to their hesitancy in relocating. Doctors who already have gone to war sometimes—and quite understandably—show a definite antipathy to permitting outside doctors to come into their home communities and take over their practice. This is illustrated by a petition from members of a county medical society in a Southern state who are now with the armed forces. The petition reads in part:

We, having abandoned our homes and practices for service in the armed forces of our country believe that we have the right to demand protection of our practices and do therefore petition that any doctor under 45 years of age moving into County immediately be put on the available list and quickly inducted into the service.

This system, whereby a physician is "put on the available list and quickly inducted into the service" after being declared not essential to his community by the Procurement and Assignment Service is one method for obtaining doctors for the Army and Navy. It is a system which, in combination with other factors, has resulted in too many doctors being taken from some sections and not enough from others. The U. S. Public Health Service can, under certain conditions, send physicians as commissioned officers into areas of need. Usually this action follows a disaster such as fire, flood or epidemic. In the present emergency the Public Health Service has sent three physicians and one dentist into critical areas. There are however no more funds available to the Public Health Service for this purpose. One of these physicians may have to be withdrawn because of budgetary restrictions. An added difficulty found in a number

of instances by the OWI is the disinclination of medical groups to allow a physician paid by the Public Health Service to practice medicine in a particular community.

The system in use at present to apportion doctors between the armed forces and the civilian population is inadequate. This system was set up in October of 1941 with the creation of the Procurement and Assignment Service, a committee of four doctors and one dentist, in the Office of Defense Health and Welfare Services. This committee, which was transferred to the War Manpower Commission the following April, was charged with supplying doctors for the armed services while maintaining an adequate supply for the civilian population.

The Procurement and Assignment Service works through state and local committees of leading doctors whose responsibility it is to declare doctors of military age either "essential" to their communities or available to the armed services. Procurement and Assignment has no authority either to assign a doctor to the armed forces or to keep him in practice in his home community. At present however neither the Army nor the Navy will grant a commission to a physician until that physician has been declared not essential to his community by Procurement and Assignment.

On April 21, 1942 the War Manpower Commission announced that the Procurement and Assignment Service had started its machinery to secure sixteen thousand physicians for the armed forces before the end of 1942 without weakening the medical structure for civil and industrial population. Of these, five thousand were to be obtained within the next sixty days. In June the goal for 1942 was increased to thirty-five thousand physicians. As the armed forces were enlarged, Procurement and Assignment could not obtain physicians rapidly enough by this voluntary method. The Army in April dispatched recruiting teams through the United States to stimulate recruiting of doctors. These teams recruited at the rate of about one hundred physicians a week. In certain cases pressure was applied to doctors who were reluctant to enter the service. If a doctor was declared not essential to his community by the Procurement and Assignment Service that doctor if within the age limit, was expected to apply for a commission. If he did not apply, his status was reported to the draft board and reclassification recommended. A Chicago physician last January was ordered by his draft board to report for induction into the Army as a private in one of the few such actions in the nation. The doctor had been declared available for military service by the Procurement and Assignment Service, and when he failed to file an application for a commission his draft board was advised by the state Selective Service medical director that he could be taken. Three deferments were granted the doctor after he reported for induction and subsequently he filed for a commission.

Usually doctors needed no pressure to enlist in the service of their country. They went because they felt it was their duty. These voluntary enlistments combined with urging by Army recruit boards resulted in severe depletion of physicians in some areas. Especially was this true of the South and of small rural communities the very places which needed their doctors most.

THE QUOTAS OF VARIOUS STATES

A quota was set in each state for the recruiting of doctors, and the states were not supposed to go beyond these quotas. In many cases they did. Procurement and Assignment committees in two Southern states were not even aware of their quotas until they were oversubscribed. Another factor in uneven withdrawals was the failure to establish the quotas until after the Army recruiting teams began their work of urging doctors to accept commissions. As of Dec. 1, 1942 thirty-eight states and the District of Columbia had gone over their quotas. Alabama went 109 per cent over, Arizona 64 per cent over, Arkansas 27 per cent over, Colorado 28 per cent over, Delaware 59 per cent over, the District of Columbia 4 per cent over, Florida 23 per cent over, Georgia 54 per cent over, Idaho 73 per cent over, Illinois 2 per cent over, Indiana 35 per cent over, Iowa 27 per cent over, Kansas 23 per cent over, Kentucky 70 per cent over, Louisiana 118 per cent over, Maine 32 per cent over, Maryland 14 per cent over, Michigan 50 per cent over, Minnesota 5 per cent over, Mississippi 63 per cent over, Missouri

15 per cent over, Montana 22 per cent over, New Jersey 18 per cent over, New Mexico 129 per cent over, North Carolina 65 per cent over, North Dakota 14 per cent over, Ohio 24 per cent over, Oklahoma 35 per cent over, Oregon 24 per cent over, Pennsylvania 5 per cent over, South Carolina 76 per cent over, South Dakota 41 per cent over, Tennessee 73 per cent over, Texas 57 per cent over, Utah 21 per cent over, Virginia 42 per cent over, Washington 40 per cent over, West Virginia 61 per cent over and Wyoming 71 per cent over. Nine states as of Dec. 1, 1942 were under their quotas. California, Connecticut, Massachusetts, Nebraska, Nevada, New Hampshire, New York, Vermont and Wisconsin. Rhode Island had just 100 per cent of its quota. The Procurement and Assignment Service has announced that recruiting of physicians for the armed forces during 1943 will take place only in those states in which no over-all shortage of physicians exists.

As far as relocations are concerned, the Procurement and Assignment Service is now doing what it can under the handicaps imposed. On December 15 last a statement by Procurement and Assignment contained this: "Procurement and Assignment Service cannot, in all probability, secure on a voluntary basis all the physicians required for private practice, for industry and for staffs in institutions and agencies. Oftentimes where the need is most acute the conditions of practice are not attractive financially or otherwise. Physicians will neither seek nor be sought by some communities where, nonetheless, medical services are needed. Under such circumstances it may be necessary to invoke compulsion." Thus far, no means of invoking that compulsion has been devised.

There are five categories in the manpower pool from which doctors can be drawn to assist the relocation process. Those possibly available are (1) physicians in communities which can 'make do' with fewer doctors, (2) interns and residents with physical disabilities which prevent military service, (3) physicians who have retired from practice but are willing to resume, (4) women doctors and (5) refugee doctors.

The Public Health Service has estimated that there are some eight thousand women physicians in the country, none of whom are at present eligible for military service. Some of the women doctors, of course, are not in practice. There are approximately six thousand refugee doctors in the country, several thousand of these are licensed to practice in the states where they reside. Because they are not citizens of the United States, they are not permitted now to accept commissions in the Army or the Navy.

Procurement and Assignment last December and January held meetings throughout the country in an effort to get doctors to relocate voluntarily to areas of need. It reported three hundred and forty physicians relocated through its efforts during 1942 and two hundred and forty seven relocated by other means.

England in the early days of the war depended, as we do now, on voluntary relocation. England now has authority to send physicians where needed on recommendation of the Central Medical War Committee, although so far doctors generally have relocated without compulsion. It should be pointed out that England—unlike the United States—has a sweeping manpower law which gives the government power to require all persons to 'place themselves, their services and their property at the disposal of His Majesty.' Thus the minister of labor may direct any person of any age to perform any service which that person is capable of performing.

Because of our federal system and the individual laws of the separate states, the problems of relocation in this country are somewhat more involved than in Great Britain. Normally a physician from one state cannot practice in another without passing that state's medical tests. There are exceptions, such as reciprocal agreements, practice by Public Health doctors under federal commission, and enactment by state legislatures of a law permitting out of state physicians licenses which would expire with the end of the emergency. Such a law has been recommended by Procurement and Assignment to state legislatures for enactment when necessary. Very few legislatures have taken action.

The personal element is also important in attempting relocations. Not only do people become accustomed to a particular doctor—"and he's the only doctor who really understands my condition"—but doctors also become attached to communities.

It is hard for a physician long established in one place to uproot himself and his family and go to another in greater need of his services. The only answer to this is, of course, that in war many things are hard for many people but they have to be done just the same. One fact which should be realized is that "luxury" medicine is out for the duration. Doctors will have to restrict their attentions to those actually in need of them, and patients must no longer insist on one particular "favorite" physician.

The problem of medical care in rural regions is quite different from the problem in cities or in large industrial areas. This is recognized by Procurement and Assignment, which has set smaller quotas of physicians for the armed forces in states whose population is distributed over many miles. Unfortunately, in many of these very states recruitment of doctors has been beyond the quotas established.

A COMMUNITY IN A SOUTHERN STATE

A typical case history of a rural community expanding under war industry with consequent intensification of medical shortages was found in a Southern state. In considering this example, as well as in considering other examples, it should be remembered that areas investigated were those where doctor scarcity had been specifically reported. The people of this community before the war were tenant farmers living in poverty. The several textile mills were, for the most part, closed during the depression years. Tuberculosis is prevalent. The manager of one of the textile mills said "The people around here have no vitality." Before the war this community had a population of approximately 40,000 and was medically undersupplied. Now the textile mills are going full blast and a large chemical warfare and an ordnance plant, supervised by the government, have located on the outskirts. There has been a huge influx of workers who are living in crowded and sometimes insanitary conditions. The population has increased to roughly 55,000. With this increase of more than 35 per cent there has been a decrease of one third in the number of effective doctors. Four went into the Army and one died recently. There is now approximately one doctor to each 3,200 persons. Of those available at present, three are 65 years old or older and one is ill and capable of only part time practice. The health department in this community has undertaken a drive to establish sanitary conditions in the most crowded sections. Many of the houses have never had toilets or running water, and workers are being jammed into shacks and abandoned stores for lack of other accommodations. As more workers move in and fatigue reduces resistance to disease, the situation may become more serious. A responsible doctor in this community told the OWI that although the doctors were very much overworked he would be reluctant to bring in "outsiders." Asked about the possibility of using women doctors, he said they "might be willing to try one." When the question of refugee doctors was brought up, the doctor replied "Absolutely not. We will not have those men coming in here, taking the places of our men in the Army."

A number of doctors questioned were against allowing refugee physicians to practice in their communities, despite the obvious need for additional medical care.

One area visited in the Middle South has a population of 12,000 and at present is entirely without a doctor. The nearest hospital—a small private one—is 20 miles away. Twenty years ago the country thereabouts was swamp and thicket. A big drainage project opened up the county and brought in land speculators. The population has increased 700 per cent in the past twenty years. Most of the inhabitants are cotton farmers. The one doctor who had been serving this entire area was recently declared nonessential to his community by Procurement and Assignment. He therefore applied for a commission as a doctor in the Army and was accepted. Before he left, however, he brought another doctor—a friend—to this community. The man was 28 years old and within a few months he also was taken by the Army.

The people of this community have tried all possible ways to get their original doctor released by the Army, but without success. They have appealed to Procurement and Assignment for a doctor willing to relocate there but none has been found. The area would not attract the average doctor. There is no

hospital, no nurse. The rough roads make travel most difficult. Frequently the regular physician before he was called to the Army, went on a night call riding on a tractor. For childbirth cases this doctor carried a folding delivery table. His wife, a trained nurse, went with him. For a clinic he had a small four room brick building next to the drugstore on the main street, of which he was as proud as another doctor might be of the finest metropolitan hospital. Now the clinic is deserted. In the small waiting room dust lies thick on the oak desk and the chairs. The examining room with its operating table, baby scales and enamel cupboard is covered with dust. The druggist next door is doing his best to carry on. Now he practices emergency medicine, for there is no one else to do it. "I may go to jail for this," he says, "but somebody has to take care of the people." The mayor of the town is standing by him—not only standing by, but helping when he has to. The night before the OWI representative visited the town a man came into the drugstore with a deep head wound. The druggist poured on iodine and pasted the gash together with adhesive tape. Another night a woman was brought in severely lacerated and bleeding profusely. The druggist got his friend the mayor and together they did what they could, keeping life in the woman until she could be taken to the hospital 20 miles away.

Rural regions which are not defense areas are finding it very difficult to obtain doctors. This particular section is not classed as a defense area, as short staple cotton is not considered a war commodity. The cities in this state are fairly well supplied with doctors and fourteen doctors have been relocated, four of them in communities where there are factories making arms and ammunition. The state Procurement and Assignment chairman has received a number of applications from doctors willing to go into war plants as industrial physicians, where they would work eight hours a day for a fixed salary. But there are few applications for relocation to rural districts, where a doctor may have to ride to his patient on a tractor.

A similar problem was found in another Southern state. In a county with a population of some 15,000, the only industry is cotton textile manufacturing. There is no war industry and no increase in population, therefore, under the present system, this section is unlikely to get emergency aid. Yet the situation here is desperate. In 1941 this county had six doctors. Three of these were taken by the Army. One of the doctors still there is 74 and suffers from a disability which limits his practice to ordering prescriptions over the telephone from druggists. Of the two doctors remaining one lives on the far eastern side of the county. On the other falls practically all the medical work of the area. He averages about three hours' sleep a night. He tells prospective mothers quite frankly that he will do the best he can for them but he cannot promise to be on hand in a crisis. In 1 case when arrangements had been made long in advance the doctor arrived three days after the birth of the child.

The women of the county take courses in home nursing and nutrition. They are doing the best they can. Through the state Procurement and Assignment the manager of the cotton mill secured the names of eleven doctors who had signified their willingness to be relocated. The manager wrote to all of them pointing out that the doctor would have charge of the mill's medical service as well as private practice and could make a minimum of \$8,000 his first year there. Only one of the eleven answered—a young man who had just finished his internship and had been rejected by the Army. He paid the county a visit. For a time hope rose high among the residents. Then one day the mill manager received a letter. Because of the lack of hospital facilities in the county the young man had decided to locate elsewhere. They are still trying to get a doctor.

A NEED FOR GENERAL PRACTITIONERS

The age of specialization in medicine also has had an effect on doctors who might be available for relocation. OWI representatives discovered time and again a need for general practitioners even in cities otherwise well supplied with doctors. In some cities it was found that the actual ratio of physicians to population was well within the one to 1,500 ratio established as a guiding figure for the nation as a whole and yet there was in reality a medical shortage because of a lack of

general practitioners many of whom were taken by the armed forces.

Brig Gen Larry B. McAfee, assistant to the Surgeon General of the Army, has stated that 65 doctors for each thousand soldiers is the lowest ratio the Army feels is consistent with efficiency. The ratio as of last December was slightly less than 8 per thousand.

As of Sept. 30, 1942, there were considered to be 135,932 effective physicians in the United States. The total number of physicians was 179,039, but some of these are of advanced age, are suffering from physical disabilities or for other reasons are not practicing. There were on active duty with the Army 31,400 with the Navy 6,104 and in the U. S. Public Health Service 1,069, a total of 38,573. Since Sept. 30, 1942, the date of this estimate, additional doctors have been enlisted. Procurement and Assignment has estimated that if the ratio of one physician to each 1,500 persons in the country is preserved—and this ratio is simply a measuring stick susceptible to variations—the maximum number of physicians who can be withdrawn from civil practice during 1943 is 11,455.

In a number of communities investigated groups of nurse's aides—patriotic townswomen who are trained to perform simple nursing duties in hospitals and clinics and thus relieve registered nurses for more important work—were of distinct help in relieving a nurse shortage. These women, many of them housewives, give patients baths, take temperatures, serve meals and carry out other routine duties which otherwise would occupy the time of a regular nurse. Efforts are being made in other communities to recruit more women for this work. As additional nurses are called for service with the armed forces, the work of these nurse's aides is becoming increasingly important.

Besides this method of alleviating the situation the OWI found many instances of "making do with what we have." These include posting the names of available doctors in prominent places, agreements among certain doctors to be on call during alternate periods of the day, teaming of doctors particularly in rural areas, so that a doctor nearest a patient will take a call, creation by doctors of an alternating system for night calls so that at least one doctor will be on duty at all times, establishment of group clinics. Public health nurses are helping with baby deliveries, doing follow up work for doctors and educating the public in child care and other health programs. Newspapers in many localities periodically campaign for public cooperation in conserving doctors' time.

In one community near a huge Army encampment this "make do" plan has been unusually successful. The situation here was similar to many others found to exist around large military training centers. Thousands of women and children, the families of soldiers and civilian workers at the camp, have invaded the area creating serious problems of housing, sanitation, water supply and eating facilities in addition to the problem of medical care. In this particular area, in which the fort is permanent but has been vastly expanded, the population of the county has increased from 26,604 in 1940 to about 40,000. There are thirteen doctors practicing in the county, nine of them in the most thickly settled area around the post. Although the ratio is roughly one doctor to 3,000 persons, this is deceptive. Eight of the thirteen doctors are 60 years old or over and one of them is 80. Four of the eight practice only half time or less. Families of service men and of civilian workers have not been eligible for medical care at the post since October 1942.

A housing development adjacent to the post has for some time been seeking a doctor but in vain. Recently this community decided to take things into its own hands. It advertised in the Army post newspaper and on the post bulletin board for registered nurses. Three responded—wives of army officers. The community hired two of these and set up an emergency aid station with the aid of Army Emergency Relief funds. The nurses have office hours twice a day, make house calls and hold a baby clinic once a week. Last December they handled 892 calls—520 at the clinic and 366 in homes. Forty-five of the calls were at night. Twenty cases were referred to a doctor obtained from another community. In the beginning supplies and equipment were lent by the post medical authorities and transportation for the nurses was supplied by the

Red Cross Now the community is providing both out of its own funds. Plans are under way to enlarge the service by opening another emergency station and hiring the third nurse. The community still hopes that a doctor will relocate there.

THE GROUP PLAN

Prepaid insurance for doctors care is being utilized by thousands of war workers particularly on the West Coast, where there are areas as critically in need of doctors as anywhere in the United States. Before the war began medical societies of two West Coast states were supporting group plans for industrial workers group plans which have proved increasingly beneficial as population figures grew. Doctors throughout these states who cooperate in the plans are assigned to care for groups of individuals and are paid by funds from the association.

The group plan in one of these states is proving especially capable of adapting itself to the rapidly changing needs of the population. Before the war medical insurance was provided for industrial workers and farmers. Now this has been extended to take care of residents of emergency housing projects. It was found that many housing units had been located in regions where the available doctors were already taxed to the limit of their endurance where the distance from the project to doctors offices was too great and where most residents were migrants unable to work out their medical care problems in new surroundings without help. For such 'rush room' communities the statewide physicians' service and the Federal Public Housing Authority have cooperated in a plan which brings onto the grounds of the housing project itself a resident doctor, who is paid on straight salary basis and nursing staff. For special care beyond the resident doctors attention, patients are referred to a panel of local physicians who cooperate in the state service program. The plan embraces a wide variety of medical treatment chronic illness hospital treatment antepartum care, childbirth and much more. The FPHA collects dues along with the rents. Thus the medical profession itself has adapted a group care plan to an important war emergency. So far it operates in four large and congested areas of this state where not quite 90 per cent enrollment of housing project residents has been reached. War workers elsewhere in the state may soon be given doctors help under this plan.

Employers holding war contracts have shown widely divergent attitudes toward safeguarding the health of their workers ranging from complete indifference to highly conscientious and efficient action. Here again the West Coast offers examples of outstanding achievement. One shipbuilder surveyed the medical facilities of the communities in which his yards were to be built just as he surveyed all other facilities which would

affect either his men or his materials and ultimately his production. In some places the local doctors and hospitals seemed numerous enough to care for the incoming workers, but in two districts where a shortage of both doctors and hospitals appeared unavoidable the employer decided to build his own hospital and hire his own staffs of doctors and nurses. Over 100,000 workers in the shipyards which these two hospitals serve pay a fee each week for medical care. This is deducted from wages. Currently nearly 150,000 treatments are given each month by seventy-two doctors and nearly two hundred and fifty nurses. In addition to the two main hospitals and one field hospital first aid stations are operated throughout the yards which provide quick attention to injuries and also offer preventive medicine which considerably reduces the illness rate and the time required away from work for treatment.

The general conclusion drawn from this investigation is that while there is not at present a serious breakdown in the health of the nation due to the doctor shortage there is a probability of slow deterioration of health in communities suffering from medical shortages. Long hours of work in war plants are a contributing factor in health breakdown. The problem of absenteeism in war factories due to illness is a serious impediment to the success of the war.

It is also evident that we can no longer afford to look tolerantly on the scarcity of medical care in rural areas. Farmers have become as important as the man on the fighting front or the man in a shell factory.

Antepartum and postpartum care for mothers has assumed added importance. And as is usual in wartime our birth rate is soaring. These new citizens must be properly cared for as must their mothers thousands of whom are working side by side with their menfolk in war plants.

The medical situation in this country as a whole is not now serious. It can however interfere with our war production unless we initiate some method of appraising the problem in its entirety and deciding on the best plan for meeting it.

The war has brought many new problems to America and has intensified old ones. Comparisons with what happened to this country during the last war are frequently invalid for this war is not like the last war. It is infinitely more difficult it involves infinitely more people. It cannot be run successfully on a makeshift basis. Whenever possible problems must be met—and in many cases are being met—before they develop into serious situations. Recognition that a medical problem exists before it reaches the danger stage is all important.

It is recognized that relocation of doctors is not the whole answer to the problem of medical care for the civilian population in wartime. Nurses hospitals clinics nutrition sanitation preventive medicine all play vital parts. To the subjects the Office of War Information may return in a later report.

MISCELLANEOUS

PUBLIC HEALTH UNDER HITLER

According to NDZ of January 20 in the *Gesundheitsführung*, the president of the Reich Board for the Fight Against Rheumatic Ailments Prof. Dr. Geronne stresses the great social importance of this work. About 12 per cent of all cases of illness in large enterprises are due to rheumatic diseases. The significance of this from the social point of view is not so apparent in the death rate as in the large number of resulting cases of heart disease. The most important problem is early diagnosis and early treatment of rheumatic ailments. Health insurance societies must be obliged to keep a special register of these cases of illness. It is necessary too to organize large sections in hospitals to deal with cases of rheumatic disease. For the time being it will probably suffice to open three or four of these special sections in each gau, with the object of procuring the best possible early treatment and, at the same time, continuing the training of doctors. The campaign against rheumatic ailments will start with the setting up of these special sections in hospitals in all gau. In addition it will be necessary later on to organize observation centers in suitable hospitals. These will collaborate with the special sections in their practical work. Finally, preventive measures must be extended by

popular enlightenment strengthening resistance promotion of physical fitness care of the teeth and hygienic working and living conditions.

NDZ of January 18 states that in the fight against tuberculosis series of x-ray examinations made with the schürm bildgerät have proved the best means of discovering the persons suffering from this disease. To insure that the scheme is carried out systematically, the Reich Health Leader has issued an order stating that the examination of the population by means of x-ray series photos will be undertaken by the x-ray sturmtrupp. These examinations include all examinations of the inhabitants of densely populated centers, especially of entire gau towns and kreise. They do not comprise examinations of certain groups of the population which are made by the health offices, or of party formations factory workers and civil servants. The Reich Health Leader has created within his office a service unit for x-ray series examinations of the people, consisting of party members Drs. Blome, Walter and Hofelder. This service unit will be responsible for the execution of the scheme.

According to Zora of January 5, the government has fixed prices for medicines and will pay the difference between the fixed price and the cost price from the equalization fund.

ORGANIZATION SECTION

THE HOUSE OF DELEGATES SESSION

AMERICAN MEDICAL ASSOCIATION, CHICAGO

BEGINNING JUNE 7, 1943

OFFICIAL CALL

TO THE OFFICERS, FELLOWS AND MEMBERS
OF THE AMERICAN MEDICAL
ASSOCIATION

The regular annual session of the House of Delegates of the American Medical Association will be held in Chicago, beginning Monday, June 7, 1943

In the House the representation of the various constituent associations for 1941, 1942 and 1943 is as follows

Alabama	2	New Hampshire	1
Arizona	1	New Jersey	5
Arkansas	2	New Mexico	1
California	8	New York	19
Colorado	2	North Carolina	3
Connecticut	2	North Dakota	1
Delaware	1	Ohio	7
District of Columbia	1	Oklahoma	2
Florida	2	Oregon	1
Georgia	3	Pennsylvania	11
Idaho	1	Rhode Island	1
Illinois	9	South Carolina	2
Indiana	4	South Dakota	1
Iowa	3	Tennessee	2
Kansas	2	Texas	5
Kentucky	3	Utah	1
Louisiana	1	Vermont	1
Maine	1	Virginia	2
Maryland	2	Washington	2
Massachusetts	6	West Virginia	2
Michigan	5	Wisconsin	3
Minnesota	4	Wyoming	1
Mississippi	2	Alaska	1
Missouri	4	Hawaii	1
Montana	1	Isthmian Canal Zone	1
Nebraska	2	Philippine Islands	2
Nevada	1	Puerto Rico	1

The sixteen scientific sections of the American Medical Association, the Medical Corps of the Army, the Medical Corps of the Navy and the Public Health Service are entitled to one delegate each

There will be no Scientific Assembly of the Association in 1943, but the President-Elect, Dr James E Paulin, will be installed as President in the Ball Room of the Palmer House, Chicago, at 8 p m, Tuesday, June 8, 1943

FRED W RANKIN, President
H H SHOULDERS, Speaker House of Delegates
OLIN WEST, Secretary

MEMBERS OF THE HOUSE OF DELEGATES
A Preliminary Roster of the Legislative Body of the
American Medical Association

The list of members of the House of Delegates for the session is incomplete as a number of the state associations are yet to hold their meetings at which delegates will be elected. The following is a list of the holdover members of the House of Delegates and of the newly elected members who have been reported to the Secretary in time to be included

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 5 p. m. Eastern War Time (4 p. m. Central War Time, 3 p. m. Mountain War Time, 2 p. m. Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 10:30 p. m. (formerly heard at 8 p. m.) Saturdays over Station WMAQ.

The titles and guest speakers for the next four programs are as follows:

April 10 Battle Stations at Home
Speaker: Col. George Baehr, Chief Medical Officer, Office of Civilian Defense

April 17 Stratosphere Flight
Speaker: Brig. Gen. David N. W. Grant, Air Surgeon, United States Army

April 24 Sharp Eyes

Speaker: Lieut. Col. Harold C. Luethi, Liaison Officer, Procurement and Assignment Service, Chicago

May 1 'Jungle Death'

Speaker: Brig. Gen. C. C. Hillman, Chief of the Professional Services Office of the Surgeon General, United States Army

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled 'Before the Doctor Comes' will be on the air every Thursday morning at 9:45 a. m. and including May 27. Common home health problems are discussed in an interview program in which Dr. W. W. Bruer, Director of the Bureau of Health Education, is interviewed by Mrs. June Merrill. The titles for the next four programs are:

April 8 What to Do About Cuts and Scratches
April 15 What to Do About Bad Bumps
April 22 What to Do About Choking
April 29 What to Do About Bleeding

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S. 400 has been reported to the Senate in an amended form with recommendation that it pass, a bill providing for the organization and functions of the United States Public Health Service. One amendment provides that for the duration of the present war and for six months thereafter graduates of reputable osteopathic colleges shall be eligible for appointment as reserve officers in the Public Health Service. S. 495, a bill to establish a Women's Army Corps for service in the Army of the United States, has been reported, with amendments, to the House of Representatives. One amendment provides that physicians and nurses shall not be enlisted in the corps. S. 675 has been reported to the Senate, a bill to amend the Selective Training and Service Act so as to extend the benefits of the United States Employees' Compensation Act to conscientious objectors. H. R. 1857 has been reported to the House with an amendment providing for the commissioning of female physicians and surgeons in the Medical Corps of the Army and Navy. The amendment strikes from the bill the restriction that such female physicians may be assigned to duty only in hospitals or other stations where female nurses are employed. H. R. 1749 has been approved by the President to amend Veterans' Regulations so as to grant hospitalization, domiciliary care and burial benefits to any person who served

in the active military or naval service of the United States on or after Dec. 7, 1941 and before the termination of the present war. H. R. 2218 has been reported to the House, a bill to provide a method for the payment currently of individual income taxes. One section of this bill proposes an additional exemption for persons in military or naval service of so much of his service pay as does not exceed the sum of \$3,500 over the personal exemption.

Bills Introduced—The President has submitted to the Congress a supplemental estimate of appropriations for the Public Health Service in the amount of \$2,294,000 for pay of personnel and maintenance of hospitals. S. 897, introduced by Senator Bailey, North Carolina, proposes an amendment to the Insecticide Act providing that any white powder insecticide or fungicide containing arsenic in its elemental form or in any of its combinations, or fluorine in any of its combinations shall, unless deemed unnecessary by the Secretary of Agriculture for the protection of the public health be deemed to be adulterated unless it is distinctly colored in accordance with regulations promulgated by the Secretary of Agriculture. S. 910, introduced by Senator Downey, California, proposes to amend the Social Security Act so as to provide that each state shall have the exclusive right to adopt its own interpretation of the phrases "needy individuals who are blind" and "blind individuals who

are needy" The purpose of the bill is to encourage the states to make more adequate provision for blind persons H J Res 103, introduced by Representative Carson, Ohio proposes the establishment of a Division for the Physically Handicapped in the United States Employment Service H R 2084 introduced by Representative Hagen, Minnesota, would extend the status of veterans of the World War to persons enrolled or enlisted and serving on United States Shipping Board vessels during the World War in war zones H R 2248, introduced by Representative Hare, South Carolina, provides for disability compensation for certain injuries sustained by civil employees of the United States government H R 2251, introduced by Representative Spence, Kentucky, proposes to create a Division of Water Pollution Control in the United States Public Health Service H R 2276, introduced, by request, by Representative Pace, Georgia, proposes an appropriation of \$1,000,000 annually for the duration of the emergency for allotment to the states to promote the development of better diets and an improved nutritional status for the people of the United States H R 2285 introduced by Representative Tolan, California, would establish an Office of War Mobilization and create therein an Office of Scientific and Technical Mobilization to effect the full and immediate mobilization of scientific knowledge, technique and personnel for the prosecution of the war and for making adjustments necessitated by war conditions

STATE MEDICAL LEGISLATION

California

Bill Introduced—S 1077 proposes the creation of a state board of naturopathic examiners and defines naturopathy as the treatment of the sick and afflicted by the use of such substances as light, air, water, clay, heat, rest, diet, herbs, electricity, massage, Swedish movements, suggestive therapeutics, magnetism and physical and mental culture Naturopaths would be authorized to execute birth and death certificates and to have the same rights as other physicians to practice under any governmental plan or system created for the purpose of providing medical care or treatment. Approved naturopathic colleges would have the right to receive dead bodies for the purpose of instruction and study in like manner and under the same provisions of law as other institutions

Connecticut

Bill Enacted—S 261 has become chapter 45 of the Laws of 1943 It amends the premarital examination law by providing that the required certificate shall be signed by a physician licensed to practice medicine or osteopathy in Connecticut or in any other state or territory of the United States or the District of Columbia

Indiana

Bill Enacted—S J Res 7 was adopted, February 26 It resolves that the general assembly go on record as urgently requesting the Congress of the United States to pass legislation to establish a pharmacy corps in the army

Iowa

Bill Enacted—S 82 was approved, March 16 It amends the income tax law by authorizing taxpayers to deduct expenses for the medical care of the taxpayer, his spouse or a dependent and defines the term medical care as amounts paid for the diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body

Kansas

Bills Introduced—H 366 proposes to extend the scope of osteopathic practice by authorizing present and future licentiates to administer and prescribe narcotics and biologicals and to register and practice under the laws of the United States governing the administering and prescribing of narcotics Biologicals are defined as medicinal preparations made from animal juices, tissues or serums H 394 proposes to require each applicant for a marriage license to present a certificate from a duly licensed physician certifying that the applicant and the proposed marital partner are, in the opinion of such physician and based on a standard serologic test for syphilis, not incapacitated to marry

Bill Passed—H 332 passed the house on March 3 and the senate on March 17 It proposes to require every physician to take or cause to be taken a sample of blood of any woman whom he diagnoses as being pregnant such sample to be taken within fourteen days after the diagnosis is made and only with the consent of the patient

Bills Enacted—H 120 was approved, March 10 It excuses physicians in the military service from renewing their licenses annually and prohibits revocation of such licenses during the period of their military service H 121 was approved March 10 It amends the medical practice act by eliminating the requirement that no two of the required four six month periods which must be spent in the study of medicine and surgery may be given within the same twelve months The purpose of this law is to enable graduates of accelerated medical courses to obtain licensure in Kansas

Maine

Bill Passed—S 304 passed the house March 10 To amend the osteopathic practice act, it proposes to authorize approved osteopathic schools to give a course of instruction for a total of thirty-six months within a three to four year period when such school has adopted compressed or accelerated courses as a war emergency measure

Maryland

Bills Introduced—H J Res 20 proposes a request to the legislative council to make a study looking toward the enactment of a law to reimburse nonprofit hospitals for expenses incurred in treating indigent patients suffering from injuries from automobile accidents H 499 proposes the creation of a state board of naturopathic examiners and defines naturopathy as a branch of the healing art embracing the diagnosis and practice of physiologic, physical, mechanical and material methods and agencies of healing The bill would further provide that nothing therein should be held or construed to authorize any naturopathic physician licensed thereunder to use drugs or surgery H 663 proposes to repeal the existing law requiring all children to produce certificates of vaccination before being admitted to any public school

Bills Passed—S 339 passed the senate March 16 It proposes to prohibit teachers from receiving into the public schools any child between the ages of 5 and 10 who does not present the certificate of a registered practicing physician of the state of Maryland or of the county health officer that such child has received an inoculation of toxoid or other approved immunizing agent to protect against diphtheria, at least one of said inoculations having been given after the age of 5 years S 360 passed the senate, March 19 It proposes that no persons shall sell, dispense or give away any drug or medicine for the treatment or cure of venereal disease or any sulfonamide drug except on the written prescription of a physician licensed to practice medicine H 524 passed the house March 12 It proposes to require the state department of health to furnish insulin to all residents who are suffering from diabetes and who are unable because of their financial condition to purchase such insulin provided that any person who is financially able to pay for the drug may obtain it from the state department of health at actual cost

Massachusetts

Bills Introduced—H 1382 to amend the law relating to aid to dependent children proposes to authorize payment for medical and hospital care to be made directly to the person furnishing such services in certain instances H 1387 proposes to authorize the department of public health to establish and maintain cancer clinics and to provide therein services and treatment for cancer

Michigan

Bills Introduced—H 250, to amend the crippled children's act, proposes among others things to limit professional fees for major operations to \$75 and to \$200 for any one physician for any one patient in any year H 266 proposes a completely new act providing for the payment of compensation to employees who sustain disabilities from injuries or diseases during the course of their employment H 343 proposes to prohibit any minor from purchasing and any person from selling to a minor any alcoholic beverage except pursuant to a prescription

or a duly licensed physician. H. 359, to amend the premarital examination law, proposes to require applicants for a marriage license to present a certificate of a reputable physician to the effect that such person is free from venereal diseases and is mentally sound. H. 373, to repeal certain sections of the existing law relating to the licensing of pharmacists and to reenact a new law on the same subject, proposes, among other things, that the phrase "practice of pharmacy" shall mean the manufacture, compounding, dispensing, sale or distribution of drugs, medicines or poisons to be used for man or other animal.

Bills Passed—S. 113 passed the senate on March 9 and the house on March 17. To amend the medical practice act, it proposes to authorize the Michigan state board of registration in medicine to suspend in whole or in part the educational requirements prescribed by the act at any time during the state of war now existing between the United States and various other nations. S. 192 passed the senate on March 9 and the house on March 17. To amend the osteopathic law, it proposes to authorize the Michigan state board of osteopathic registration and examination to modify, by order, the educational requirements prescribed by the present act, during the present emergency. H. 264 passed the house, March 11. It proposes that, where persons entitled to hospital service under a contract for such service are unable to obtain admittance to any hospital because of lack of facilities or accommodations, such contract may provide a method by which such persons may be reimbursed in whole or in part for the expense of nursing and other nonmedical care restricted to the equivalent of hospital care required from the illness or injury entitling such person to hospital service. H. 277 passed the house, March 20. It proposes to prohibit druggists and pharmacists from selling barbituric acid and any of its derivatives, chloral hydrate or paraldehyde except on prescription of a licensed physician, dentist or veterinarian.

Minnesota

Bills Introduced—S. 703 proposes to amend the law prohibiting any county official or deputy or clerk or such official from being directly or indirectly interested in any contract work, labor or business to which the county is a party or in which it may be interested in the furnishing of any article or the purchase or sale of any property or of which the construction, price or expense is payable from the county by excepting therefrom county coroners, their deputies or county physicians, for medical services performed by them for indigent persons receiving public relief or in appearing in insanity or incompetency hearings. S. 764 proposes to prohibit any persons from practicing or holding themselves out as practicing the Sister Kenny technique of treating infantile paralysis without first being authorized so to do and further proposes that any registered nurse who has received at least two years' additional training in an accredited institute or hospital using such technique may, on receiving a degree from said institute or hospital engage in such practice. S. 825 to amend the law relating to coroners, proposes that any coroner or deputy coroner who is a duly licensed and registered physician and surgeon shall not be disqualified from rendering medical care or hospitalization to a recipient of public relief, from being appointed an examiner in insanity or incompetency hearings or from being compensated therefor. H. 334 proposes to authorize licensed insurance companies to write policies to insure against loss or damage for medical, hospital, surgical or funeral expense. H. 362 proposes to prohibit the operation of a nursing home, convalescent home and rest home for hire without being authorized so to do by the commissioner of charities and corrections. H. 578 and S. 581 propose to authorize any subordinate lodge of a fraternal organization to provide medical services for members and their families and to contract with physicians to perform such services. H. 718 and S. 564 propose to transfer from the director of social welfare to the director of public institutions all powers and duties respecting mental hygiene work. H. 935 proposes to amend the law requiring corporations to be licensed before being authorized to operate a hospital nursing home or

the like by including municipal corporations, and all state subdivisions, departments, boards and agencies. H. 979, to amend the law relating to the fees of coroners, proposes that physicians called by the coroner to make an autopsy shall be allowed a fee of \$15 per day plus mileage and that a coroner or deputy coroner who is a duly licensed physician and surgeon shall not be disqualified from rendering medical care or hospitalization to a recipient of public relief, from being appointed an examiner in insanity or incompetency hearings, or from being compensated therefor. H. 985 proposes to transfer from the director of public institutions to the director of social welfare all powers and duties with reference to the state sanatorium for consumptives.

Bill Enacted—H. 273 has become chapter 121 of the Laws of 1943. It provides that physicians in the armed forces shall not be required to renew their annual licenses during the term of such service and shall be exempt from payment of all renewal fees.

Montana

Bills Enacted—S. 63 has become chapter 102 of the Laws of 1943. It authorizes certain institutions of higher learning in Montana to obtain on loan of unclaimed human bodies for use in the teaching and demonstration of anatomic science by professional instructors. S. 97 has become chapter 106 of the Laws of 1943. It relieves physicians in the military service of the United States from paying annual license fees during the period of such service. H. 91 has become chapter 125 of the Laws of 1943. It authorizes the creation of a division of Dental Health under the supervision of the state board of health, the director to be a regularly licensed dentist who shall have had at least one school year of training in an accredited school of public health and the duties of the new division shall be the development and promotion of those activities which result in the protection and improvement of the dental health of the people of the state. H. 118 has become chapter 132 of the Laws of 1943. It amends the medical practice act by authorizing the board of medical examiners to prescribe and enforce reciprocity requirements current with changes in standards of the practice of medicine and surgery. H. 128 has become chapter 126 of the Laws of 1943. It authorizes state, county and local health officers to detain and examine prostitutes and females suspected of engaging in promiscuous sexual intercourse who are infected or thought to be infected with a venereal disease and to require such persons to report for treatment until cured. Such examinations may be repeated as often as deemed advisable or desirable. H. 134 has become chapter 225 Laws of 1943. It amends the law relating to the state board of health by increasing the membership thereof from five to seven, the two additional members to be the president of the Montana state board of pharmacy and the president of the Montana state board of food distributors. It also decreases from five to three years the term of office of the members of such board. H. 245 has become chapter 165 of the Laws of 1943. It amends the law governing insane asylums by providing among other things that it shall be the duty of the hospital medical staff to examine all patients who have curable diseases every six months and to file a written report thereon.

Nebraska

Bill Introduced—Legislative bill 417 proposes to authorize the board of control to place in the Nebraska Institution for the Feeble-minded any spastic person when on written application and after due investigation the board is of the opinion it is for the best interests of such person. The proposal would further require that a separate ward for spastic persons be provided at such institution.

Bill Passed—Bill 40 passed the house, March 23. It proposes to require each applicant for a marriage license to present a certificate signed by a duly qualified physician licensed to practice medicine and surgery in any state or United States territory certifying that the applicant is not infected with syphilis in a communicable stage.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARKANSAS

Personal—Dr. William H. Toland, Nashville, has been appointed health officer for Howard County.—Dr. Henry E. Mobley has been elected a director of the Morrilton Chamber of Commerce.—Dr. William G. Hancock, Rison, has been named health officer of Cleveland County.

State Medical Meeting—The Arkansas Medical Society will hold its annual session in Little Rock, April 19-20. Dr. Rufus B. Robins, Camden, is president of the association. The program includes the following speakers:

Dr. John Harry Hayes, Little Rock, Analysis of Thyroid Surgery
Dr. Merlyn J. Kilbury, Little Rock, Leukemia and Aleukemic Diseases
Dr. Allie C. Kolb, Little Rock, Care of the Insane in the State of Arkansas
Dr. Davis W. Goldstein, Fort Smith, Industrial Dermatoses
Dr. Robert L. Sanders, Memphis, Tenn., Surgery of the Gallbladder and Common Duct
Dr. John H. Musser, New Orleans, The Doctor's Heart.
Dr. F. Walter Carruthers, Little Rock, New Concepts in the Diagnosis and Treatment of Poliomyelitis
Dr. Louie G. Martin, Hot Springs, National Park, A Safe and Sane Method of Treatment in Neurosyphilis

CALIFORNIA

New Secretary of California Board of Examiners—Dr. Frederick N. Scatena, Sacramento, has been elected secretary-treasurer of the California Board of Medical Examiners. He succeeds Dr. Charles B. Pinkham, Sacramento, who retired on February 1 after thirty years' continuous service to the state (THE JOURNAL, January 23, p. 270). Dr. Scatena, who has been a member of the board since 1941, graduated at the University of California Medical School, San Francisco in 1914. Dr. John R. Walker, Fresno, was recently appointed to the board by the governor to succeed Dr. William A. Swinn, Los Angeles, whose term expired.

Arrested for Impersonating a Physician—Reginald T. King was recently arrested for impersonation of an army officer by agents of the federal bureau of investigation, the Los Angeles Daily News reported. He was said to be wearing a caduceus on his army uniform at the time of his arrest. The report stated that King had "dressed himself up in an army uniform, posed as an officer of the medical corps, went lecturing at a high school, assumed the privileges of a doctor in a hospital, attended medical conferences and was very generally accepted." At one time he was a laboratory and x-ray technician in the office of a physician in Vallejo and was listed in the telephone directory as Dr. R. B. King, 327 Georgia Street. He is reported to have been arrested for practicing medicine without a license and to have served a sentence of nine months in the Los Angeles County Jail. Investigations by the FBI revealed that "he was a doctor at the Naval Pacific Air Base Hospital in Hawaii from June to October 1941," when he was asked to resign. On Dec. 12, 1941 he was arrested by military police and later sentenced by a military tribunal to prison. Court evidence showed that he was not a doctor of medicine but a registered nurse. It is alleged that King used many aliases including Theodore King, Theodore Bullock and Reginald Belford King.

FLORIDA

State Medical Meeting—The seventieth annual meeting of the Florida Medical Association will be held at the George Washington Hotel, Jacksonville, April 15-16, under the presidency of Dr. Gilbert S. Osmeup, Orlando. Dr. Charles W. Roberts, Atlanta, will address the first general session on "Medical Stewardship in War and Peace." Dr. George Baehr, chief medical officer, U. S. Office of Civilian Defense, Washington, D. C., will speak at the second general session on "British and American Experiences in Civil Defense." Col. Sanford W. French, M. C. U. S. Army, will address the third general session on "The Doctor in the War Effort." Reference committees and the house of delegates will hold sessions on Thursday. The association dinner will be held Thursday evening and the election and installation of new officers will be held following the third general session on Friday.

GEORGIA

Conservation of Manpower—A series of industrial health institutes for the conservation of manpower was held in Augusta on March 11, Savannah on March 12, Atlanta on March 15 and Columbus on March 16. The program was sponsored by the Medical Association of Georgia, the state department of public health and the Associated Industries of Georgia and was designed for the physician, industrial management and industrial labor. The local medical society and health department and chamber of commerce cooperated in each institute. Among the speakers who participated in the programs were:

Dr. Thomas F. Abercrombie, Atlanta, Community Health Problems Affecting Industry
J. J. Bloomfield, sanitary engineer, U. S. Public Health Service, Bethesda, Md., Wartime Health Problems Within Industry
Dr. Lester M. Petrie, Atlanta, Health Services Available to Industry in Georgia
A. J. Schroder II, personnel manager, Brunswick Pulp & Paper Company, Brunswick, Management's View of the Physician's Function in Industry
W. Cicero Kendrick, editor of the Journal of Labor, Atlanta, Labor's View of Industrial Health
Dr. Lloyd Noland, Fairfield, Ala., Recent Developments in the Handling of Industrial Injuries
F. Ruth, public health nursing consultant, industrial hygiene section, National Institute of Health, Bethesda, Nursing Aspects of Health Program for Industry
J. G. Williams, DDS, director of the division of dental health education, state department of public health, Atlanta, Dental Aspects of Health Program for Industry
Dr. Carl M. Peterson, Chicago, secretary of the Council on Industrial Health, American Medical Association, Medical Aspects of Health Program for Industry
Dr. Raymond Hussey, Baltimore, Occupational Diseases and Their Control

ILLINOIS

Dr. Pettit Chairman of Cancer Board—Dr. Roswell T. Pettit, Ottawa, was recently elected chairman of the advisory board to the division of cancer control in the state department of public health to succeed Dr. David J. Davis, dean of the University of Illinois College of Medicine.

Chicago

The Capps Prize—The Institute of Medicine of Chicago announces that competition is now open for the annual Joseph A. Capps Prize of \$400. Graduates of Chicago medical schools who completed full internship or one year of laboratory work in 1941 or thereafter are eligible. The prize is for investigation in medicine or in the specialties of medicine and may also be in the fundamental sciences, provided the work has a definite bearing on some medical problem. Manuscripts must be submitted to the Secretary of the Institute of Medicine of Chicago, 80 East Randolph Street, not later than December 31.

KENTUCKY

Occupational Diseases Now Reportable—The reporting of occupational diseases is now required by law in Kentucky, according to Industrial Medicine. Thirty-four diseases in this classification have been declared dangerous to the public health, it was stated.

Doctors Day—Doctors Day, honoring all members of the medical profession in Kentucky, will be observed by the woman's auxiliary to the Kentucky State Medical Association on April 13, giving special recognition to Dr. William A. McDowell, Cynthiana, author of A Demonstration of the Curability of Pulmonary Consumption in All Its Stages—Comprising An Inquiry into the Nature, Causes, Symptoms, Treatment and Prevention of Tuberculosis Diseases in General. The book was published in Louisville by Prentice and Weissinger in 1843.

MASSACHUSETTS

Dr. Thorn Given Chancellor's Medal for Achievement—At the recent graduation ceremonies of the University of Buffalo the chancellor's medal, awarded annually by the university council for outstanding achievement, was presented to Dr. George W. Thorn, Hershey professor of the theory and practice of physics in the Harvard Medical School and physician in chief of the Peter Bent Brigham Hospital, Boston.

New Health Officers—Dr. Harold W. Stevens, Middleboro, was recently elected president of the Massachusetts Public Health Association to succeed Dr. Henry D. Chadwick, William, who retired after two terms. Other officers include Drs. Lawrence Jackson Smith, Springfield, and Charles F. Wilmsky, Boston, vice presidents, and Raymond S. Patterson, Ph.D., who was chosen secretary to succeed G. Donald Buckner, S.B., Worcester, who retired on account of his removal to Worcester to become secretary of the Southern Worcester County Health Association. Mr. Buckner had held the secretaryship since 1934.

MICHIGAN

Personal—William J. Burns, LL.B., executive secretary of the Michigan State Medical Society, Lansing, has been appointed a member of the public relations committee of the State Bar of Michigan.—Dr. Wilfrid Haughey, Battle Creek, has been elected editor of the *Journal of the Michigan State Medical Society*, succeeding Dr. Ray H. Holmes, Muskegon, who has entered army service.

Changes in Health Personnel—Dr. N. Berneta Block, Lansing, a member of the staff of the state department of health since 1937, has been named director of the Alger-Schoolcraft health department with headquarters in Manistiquette. Dr. Block succeeds Dr. Jean B. Ruhl-Koupal, who has been named director of health district number one including Crawford, Kalkaska, Missaukee and Roscommon counties.

Motor Vehicles Lead Accidental Deaths—Motor vehicles accounted for 1,295 deaths in 1942 out of the total of 3,591 accidental deaths for Michigan as a whole. Although leading the list of accidental deaths, this is the smallest total in this group in the last nine years. Accidents in the home were second in the list of causes with a total of 1,254 deaths. According to an announcement from the state department of health, 366 occupational deaths are listed in the accidental death summary as follows: manufacturing 94, agricultural 81, transport and public utilities 47, extractive industries (others than mining and quarrying) 28, construction 22, mining and quarrying 19, trade 18, clerical and professional service 3 and all others 54.

MISSOURI

State Medical Meeting—The Missouri State Medical Association will hold its annual session in St. Louis, April 18-20, under the presidency of Dr. Homer L. Kerr, Crane. The preliminary program includes the following discussions: the sulfonamides by Drs. Henry L. Barnett, St. Louis, and Walter S. Sewell, Springfield, burns by Drs. Robert Elman, St. Louis, Francis T. H'Doubler, Springfield, and Earl C. Padgett, Kansas City, poliomyelitis by Lloyd R. Jones, Ph.D., St. Louis, Drs. John Albert Key, St. Louis, and Damon O. Walthall, Kansas City, industrial medicine as related to physical examination and industrial hazards by Dr. Edwin C. Funsch, St. Louis, syphilis by Drs. Joseph F. Bredeck and Arthur W. Neilson, St. Louis, anesthesia by Drs. Joseph A. McNearney, St. Louis, and Paul H. Lorhan, Kansas City, respiratory disease by Drs. Robert A. Moore and Henry Pinkerton, St. Louis, and a discussion on transfusions by Drs. Carl V. Moore and Raymond O. Muehler, St. Louis.

NEW YORK

Teaching Day on Chemical Warfare—A teaching day for physicians and nurses on "Medical Aspects of Chemical Warfare" will be held at Syracuse University College of Medicine, April 9. Consisting of a three-hour review session with discussion of new developments, the instruction will be presented by the college of medicine in cooperation with the health preparedness commission of the state war council, the Medical Division of the Office of Civilian Defense and the state department of health.

Commissioner of Mental Hygiene Resigns—Dr. William J. Tiffany, Albany, has resigned as commissioner of mental hygiene, effective April 1. A graduate of Columbia University College of Physicians and Surgeons, Dr. Tiffany has been in charge of the state department of mental hygiene since 1937. He entered the state hospital service in 1906 and served on the staffs of the Binghamton State Hospital, Binghamton, the Manhattan State Hospital, New York, and the Kings Park State Hospital, Kings Park, of which he was made superintendent in 1926. In 1931 he was appointed head of the Pilgrim State Hospital, Brentwood.

Program on Plasma Therapy and Blood Transfusion—Plans have been completed to present to the medical profession of the state the latest information on blood therapy and whole blood transfusion under the auspices of the state medical society, the Office of Civilian Defense, the Health Preparedness Commission of the State War Council and the state department of health. Expenses of the speakers are to be paid by the state medical society and the state department of health. The lectures may be arranged as special single sessions or in connection with formal courses or for a special or regular meeting of county medical societies. The physicians available for lectures and demonstrations attended a meeting on February 26 in the State Office Building, Albany, to hear discussions on plasma therapy and whole blood transfusion.

New York City

The Seventh Harvey Lecture—Dr. Oswald H. Robertson, professor of medicine, University of Chicago School of Medicine, will deliver the seventh Harvey Society Lecture of the current series at the New York Academy of Medicine on April 15. His subject will be "Sterilization of Air with Glycol Vapors."

Navy Officers Study Hygiene to Protect Workers—A group of naval officers are studying industrial hygiene for the protection of civilian workers in shipyards, arsenals and other naval stations at the De Lamar Institute of Public Health, Columbia University College of Physicians and Surgeons. The sixteen medical officers will train for three months at Columbia. The course will include the study of the causes of absenteeism, occupational skin diseases, ventilation and temperature, and the hazards present in toxic volatile materials in the manufacture of explosives.

Postgraduate Courses—The Long Island College of Medicine and the Medical Society of the County of Kings, Brooklyn, opened a spring program of postgraduate courses in March. Subjects covered by the series include regional anesthesia, allergy, clinical cardiology, electrocardiography and clinical cardiology, gastroenterology, diseases of the peripheral blood vessels, peripheral vascular diseases, diabetes hypertension and nephritis, female sex endocrinology, gynecologic pathology, endocrine diseases and disorders in children and adolescents, diseases of children, cardiovascular roentgenology, x-ray diagnosis, fractures, proctology and urology.

VIRGINIA

Annual Spring Graduate Course—The Gill Memorial Eye, Ear and Throat Hospital, Roanoke, will conduct its seventeenth annual spring graduate course in ophthalmology, otology, rhinology, laryngology, faciomaxillary surgery, bronchoscopy and esophagoscopy, April 5-10. Among the speakers will be:

- Dr. Theodore F. Walsh, St. Louis: Prophylaxis and Treatment of Upper Respiratory Infections.
- Dr. John K. Lindsay, Chicago: Management of Acute Suppuration in the Middle Ear and Petrous Pyramid Including Common Complications.
- Rear Admiral Luther Sheldon Jr., medical director U. S. Navy Washington, D. C.: Relationship of Otolaryngology to Naval Medicine.
- Dr. Perry G. Goldsmith, Toronto: Commentary on the Relationship Between Acute and Chronic Diseases and General Medicine.
- Lieut. Comdr. Charles H. Best, R. C. N. V. R.: Toronto Physiology in War Medical Research.
- Dr. John R. Richardson, Boston: Applied Anatomy of the Head and Neck.
- Dr. French K. Hansel, St. Louis: Diagnosis of Allergy of the Nose and Paranasal Sinuses.
- Dr. Albert A. Cinelli, New York: Treatment of Recent Fractures of the Nose and Fractures Extending into the Maxillary Accessory Sinuses.
- Dr. F. Bruce L. Likel, Ann Arbor, Mich.: Surgical Anatomy of the Eye and Adnexa.
- Dr. Peter C. Kronfeld, Chicago: Classification of Glaucoma.
- Dr. George P. Guibor, Chicago: Physiologic Principles Used in the Diagnosis of Motor Disturbances and Their Practical Applications.
- Dr. John M. McLearn, New York: Intraocular Tumors and Recent Advances in Their Treatment.
- Dr. Robert J. Masters, Indianapolis: Practical Application of Silt Lamp Microscopy in Routine Practice of Ophthalmology.
- Dr. Albert L. Brown, Cincinnati: Ocular Therapeutics.
- Dr. Rymon Castroviejo, New York: Lid Surgery.
- Dr. Willis S. Knighton, New York: Refraction Routine Procedures.

The annual banquet will be held at the Hotel Roanoke, Tuesday, April 6, with an address by Drs. James A. Babbitt, Philadelphia, and Warren F. Draper, assistant surgeon general, U. S. Public Health Service, Washington, D. C., on "Problems of Current Interest in Public Health and Medical Care for the Civilian Population."

WISCONSIN

Registry of Tropical and Exotic Diseases—Dr. Harry Beckman, professor of pharmacology, Marquette University School of Medicine, Milwaukee, is working on the establishment of a registry of all cases of tropical and exotic diseases such as malaria, Weil's disease, filariasis, relapsing fever, giardiasis, strongyloides dysentery, fluke and rare worm infections, histoplasmosis and endemic flea-borne typhus. Any physician reporting such cases to Dr. Beckman will be given credit the information to be placed in the archives of the American Society of Tropical Medicine and prepared as a compilation of cases for Wisconsin.

Industrial Clinic—The second postgraduate industrial medical and surgical clinic will be held at the Loraine Hotel, Madison, May 5, and at the Conway Hotel, Appleton, May 6. "Keep 'em Working" is the theme of the clinic as it was for the first one held last November. In addition to the scientific program which has been arranged for physicians, a special

program has been arranged for employers, nurses, personnel directors and others interested in industrial health problems. The clinic is sponsored by the council on scientific work and the committee on industrial health of the state medical society and the industrial hygiene unit of the state board of health.

Distinguished Service Pin Awarded to State Cancer Commander—Mrs G E Stoddart Beaver Dam, regional deputy commander and state commander of the Wisconsin division of the Women's Field Army of the American Society for the Control of Cancer, was presented with the society's distinguished service pin during its recent meeting in New York. The decoration, which was given for outstanding service during the previous year in the cause of cancer control, is presented annually. Mrs Stoddart is the second Wisconsin woman to be so honored. Mrs Frederick H Clausen, Horicon, was awarded the pin in 1939 in recognition of her efforts in establishing the *Bulletin* of the Women's Field Army of Wisconsin.

GENERAL

Dental Association Moves—The American Dental Association has moved into a new five story building at 222 East Superior Street, Chicago.

Journal of Aviation Medicine—With the beginning of volume 14 (February issue) the *Journal of Aviation Medicine* will be published six times a year instead of four.

Dr Weed Named Chairman of Red Cross Advisory Committee—Dr Lewis Hill Weed, professor of anatomy, Johns Hopkins University School of Medicine, Baltimore, has been made chairman of the Medical and Health Advisory Committee of the American Red Cross.

Hospital Standards Bureau Publishes Service Bulletin—The Hospital Bureau of Standards and Supplies, New York, brought out a new monthly service bulletin in January called the *Bureau News*. The first issue contains announcements concerning threatened food shortages, frozen and dehydrated foods, coffee stretchers and point rationing, discussions on various hospital necessities and consideration of miscellaneous subjects of interest to buyers and managers.

Women's Work Clothes Standardized—The American Standards Association has been requested by the Office of Price Administration to initiate a war project to standardize women's work clothes. The request carries the endorsement of the War Production Board and seeks among other things a standard to protect the workers adequately against specific occupational hazards, thus preventing accidents and reducing absenteeism resulting from accidents.

Cancer Control Month—President Roosevelt has designated the month of April as "Cancer Control Month" and, in his proclamation on March 22, called on the governors of states, territories and possessions to authorize local observances. The President also asked the medical profession, schools and colleges, press, radio, motion picture industry and all agencies and individuals interested in a national campaign for the control of cancer to spread the knowledge of the early symptoms of the disease and to publish information about the location and function of clinics and other health facilities engaged in the warfare on cancer.

Survey Shows Opposition to Hospital Plan—Results of a survey completed by *Hospital Management* reveal overwhelming opposition to the proposed expansion of the Social Security plan to cover hospitalization and a corresponding opinion that the voluntary "Blue Cross" plans can meet the need for hospital insurance. According to *Hospital Management* the survey shows a strong vote in favor of expanding the Social Security old age and survivorship benefits to cover hospital employees and a considerable majority in favor of federal aid to the states for the hospitalization of the indigent as preferable to a federally operated hospitalization plan. The survey indicates that "the doors of the hospital are open to all, regardless of the ability of the patient to pay and regardless of the fact that approximately one out of eight localities has no form of aid to the hospital for such cases. In 7 out of 8 cases some form of aid ranging from tax supported hospitals to payment of a part of the cost to voluntary hospitals, is provided for the care of the indigent sick."

Response to Requests for Parasitological Specimens—The Distributing Center for Parasitological Specimens formed under the auspices of the National Research Council and the Association of American Medical Colleges in October 1942, wishes to acknowledge the cooperation displayed by various institutions in sending specimens. Considerable material has been forwarded to the center and is being distrib-

uted to the various medical schools teaching tropical medicine and parasitology in accordance with their requests. The center is located at the Army Medical School, Army Medical Center, Washington, D C, and is operated by the school's department of parasitology and tropical medicine. The center was set up as a collecting and distributing agency for gross and microscopic specimens of value to medical schools needing additional material for the teaching of tropical medicine. The center wishes to acknowledge the following institutions, departments and/or individuals for their generous cooperation in supplying much needed material.

More than 1,200 items had been shipped to fifty-seven institutions on February 12. All shipments are sent as gifts. Major George W Hunter III, sanitary corps, U S Army is in charge of the Distributing Center for Parasitological Specimens.

Activities of Nutrition Foundation—The Nutrition Foundation Inc, has authorized grants totaling \$148,550 including \$110,700 for the renewal of twenty-eight projects supported by the foundation during 1942 and \$37,850 for fifteen new research projects. The announcement followed a meeting of the board of trustees at the Waldorf-Astoria Hotel, New York, March 12. The foundation has given \$316,000 in research grants to forty universities since its organization a year ago. Institutions which received new grants were the University of Wisconsin Madison, Harvard University, Cambridge, Mass, University of Toronto, Columbia University, New York University of California, Berkeley, Johns Hopkins University, Baltimore, New York University, Massachusetts State College, Amherst University of Chicago, Yale University, New Haven, Cornell University, Ithaca, Oregon State College, Corvallis, and Oklahoma Experiment Station, Stillwater. Oliver C Carmichael, LL D, chancellor of Vanderbilt University, Nashville Tenn, and Dr Frank G Boudreau, New York executive director of the Milbank Memorial Fund and vice chairman of the Committee on Food and Nutrition of the National Research Council, were chosen public members of the foundation, and Dr Virgil P W Sydenstricker, Augusta professor of medicine, University of Georgia School of Medicine, was appointed a member of the scientific advisory committee. The Container Corporation of America, Chicago and the Pillsbury Flour Mills, Minneapolis, were elected founder members. The National Sugar Refining Company, New York, P Duff & Sons, Pittsburgh, R B Davis Company, Hoboken, N J and the Curtiss Candy Company, Chicago, were elected sustaining members. New members of the board of trustees, representing the new members of the foundation, were announced as follows: Ellsworth Bunker, president, National Sugar Refining Company, Walter P Paepcke, president, Container Corporation of America, William H Duff II, president, P Duff & Sons Inc, B E Snyder, treasurer, R B Davis Company, Philip W Pillsbury, president, Pillsbury Flour Mills Company, and Otto Y Schnering, president, Curtiss Candy Company. Among the more important studies in which progress has been made is one carried on by William C Rose, Ph D of the University of Illinois, Urbana, and bearing on the human requirement of amino acids the "building blocks of proteins," which occur in such foods as milk, meat, eggs and fish. Coincident with Dr Rose's work showing specific amino acids to be essential in human nutrition, Vincent du Vigneaud, Ph D, Cornell University Medical College, New York, has clarified some of the important functions of amino acids in the human body, following earlier studies on the effects of these same acids on experimental animals. Other studies in which excellent progress has been made include the problem of applying fats to the armed forces in all sections of the world on nutrition problems relating to aviation and desert warfare and on the effect of extremes of environment on nutritional requirements.

Foreign Letters

LONDON LETTER

(From Our Regular Correspondent)

Feb 20 1943

Stamping Out of an Imported Outbreak of Smallpox

Smallpox has been stamped out of this country, but cases arrive from time to time from other countries. A ship from Bombay and Capetown docked on May 29 at Glasgow with 1000 passengers and 200 crew. A sick engineer was found to have confluent smallpox which proved fatal. All on board were immediately vaccinated but on June 23 another 7 of the crew, 2 passengers and a contact medical officer had developed the disease. This was disappointing for in 5 of the cases vaccination must have been done early in the incubation period—between the first and fifth days—when it usually confers protection. On the other hand, smallpox did not attack any of the 163 members of the crew who had been vaccinated on a previous voyage in 1940. Of those attacked 1 was a Polish officer who had been vaccinated nine years previously for the third time, while the medical officer, aged 34 had been vaccinated in infancy. The other 8 had never been vaccinated.

The sequel was alarming. From June 26 onward, cases of smallpox cropped up in different parts of Glasgow without any apparent connection with the ship or with one another. At first only the usual precautions were taken: contacts and neighbors were kept under surveillance and were offered vaccination so as to form a cordon of protected persons round each focus of infection. But the foci multiplied and the situation was deemed so serious as to require vaccination on a large scale. Twenty-five vaccination stations were opened, to which 282,255 persons came in the first week of July. Including those attending private physicians it is believed that half a million were vaccinated during the month.

In view of the virulence of the infection, which was fatal in 6 out of 25 cases, the usual single stroke method of vaccination was abandoned for three strokes $\frac{1}{8}$ inch long and $\frac{1}{8}$ inch apart. It was also felt that unless there was a history of recent vaccination a single unsuccessful attempt should not be taken as evidence of immunity and vaccination was repeated if no reaction was seen within four days. These comprehensive measures were successful. The 21 apparently primary cases gave rise to only 4 secondary ones and by July 31 the outbreak had ceased.

The Glasgow health officer points out that much would be gained if ships' doctors could diagnose smallpox at once and vaccinate all on board. But it is still better to immunize before the disease breaks out, and he holds that all passengers and crews from Eastern ports should be vaccinated as a condition of travel.

American War Blinded to Be Cared for at St Dunstan's

The institute for those blinded in the war known as St Dunstan's was founded twenty-five years ago by Sir Ian Fraser, who was blinded in the first world war and has presided over its activities ever since. His recollection is that fear of blindness is the worst part of eye injuries. It is an economic fear and a fear of loneliness and dependence. To avoid this reaction any one whose eyes are seriously damaged should go to St Dunstan's which is a training center where they will see others who have overcome the handicap of blindness incurred in the first world war. They act as instructors in braille, type-writing, shorthand, massage, joinery and other handicrafts. Living in a world of the blind the newcomers soon begin to concentrate on the things they can do and forget the things they cannot do. They are amazed at the variety of occupations open to the blind. They quickly learn to read, write and get about by themselves. Not all those admitted become blind

St Dunstan's has a hospital and half the patients admitted have left after a few months' treatment with vision sufficiently restored to go back to military or civil life. St Dunstan's has, with the consent of the German authorities and with the help of the Red Cross, established a school in Germany for blinded British prisoners of war. It has been arranged that American blinded in the war are to be admitted to St Dunstan's.

In a luncheon at St Dunstan's Sir Ian Fraser said that in this war presumably owing to the increased use of armor in tanks and planes, fewer men were blinded by fragments of metal than in the last war. But a larger proportion were blinded by concussion causing collapse of the eye or irreparable damage from hemorrhage. About 288 had come under the care of St Dunstan's in this war. Of these 88 had recovered some useful sight and 200 would not recover any sight at all. Of the 200, half are being trained or have been trained at St Dunstan's and 30 are in Germany as prisoners of war. It has been arranged that all American soldiers who may be temporarily or permanently blinded shall be sent to St Dunstan's for three to six weeks while awaiting to return home. Brig Gen Paul Hawley, chief surgeon of the United States Army in the European theater of operations, said that the great shock to the blinded American soldier would come when he returned home handicapped and helpless to his family. Now he would be able to return after his St Dunstan's training walking with confidence and facing the world with courage.

Annual Congress of Ophthalmological Society

Another illustration of the fact, shown in previous letters, that we do not allow the war to interfere with normal activities when they do not impair our fighting powers is shown by the holding of the annual congress of the Ophthalmological Society in London, which will be held on April 30 and May 1. Discussions will take place on "Thyrototoxicosis in Its Relation to Ophthalmology," to be opened by Dr Russell Brain and Mr H. L. Savin, and on "The Scientific and Clinical Aspects of Night Vision," to be opened by Prof W. J. B. Riddell and Air Commodore P. C. Livingstone.

Men with Amputations in German Prison Camps

The temporary artificial limbs supplied by the Germans to British prisoners were found to be badly fitting. For a time the Red Cross sent limbs by post in response to measurements. This was not successful, so last year it obtained permission to visit the camps and make a survey. Swiss orthopedic specialists were sent and worked out every detail for 430 men. They suggested that a new set of limbs should be made by Swiss experts who would visit the camps and fit them. This is being done.

New Appointment for Professor Ryle

Dr J. A. Ryle, regius professor of physics, University of Cambridge, has been elected professor of social medicine at Oxford.

Marriages

JAMES W. CHAMBERS, Fort Riley, Kan., to Miss Mollie Bauman of Des Moines, Iowa, in Whittemore, Iowa, February 4.
RUDOLPH MATAS LANDRY, New Orleans, to Miss Jane Eleanor Willius of Rochester, Minn., February 27.

HOWELL HOOD SHERRON, Johnson City, Tenn., to Miss Alice E. Simpson at Strawberry Plains, February 26.

THOMAS NOBLE WARREN, Wilmington, Del., to Miss Jean Duncan Drysdale of Lynchburg, Va., March 1.

PIERRE FABIAN LA BORDE JR., Columbia, S. C., to Miss Virginia Adams of Charleston in March.

JOHN RANDOLPH KIGHT, Norfolk, Va., to Miss Nancy Pearis Edgar of Charlottesville, March 6.

GUY O. PFEIFFER, O'Fallon, Ill., to Miss Mary Kathryn Kubitschek of St. Louis, March 9.

Deaths

Charles Francis Yerger, Chicago, Ph G, Northwestern University School of Pharmacy, Chicago, 1898, M D, Northwestern University Medical School, Chicago, 1905 member of the Illinois State Medical Society, in 1930 joined the faculty of Loyola University School of Medicine as a clinical instructor in ophthalmology and later became an associate clinical professor of ophthalmology, formerly instructor in medicine instructor in operative surgery, instructor and associate in laryngology, rhinology and otology at the University of Illinois College of Medicine instructor in otolaryngology at Rush Medical College, 1912-1913, specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology, member of the Chicago Otolaryngological Society and the Chicago Ophthalmological Society, for many years on the staff of the Illinois Charitable Eye and Ear Infirmary, attending physician to the Juvenile Detention Home and Juvenile Court since 1914, served as attending otolaryngologist and ophthalmologist to the Cook County Hospital, attending ophthalmologist to the Chicago State Hospital and the Lutheran Memorial Hospital, on the staff of the Hospital of St Anthony de Padua, a medical examiner of the Cicero Selective Service Board, 1917-1918, aged 63, died, March 16, of uremia and hypertension

Ezra Kimball Sprague * Medical Director, U S Public Health Service, retired, Brooklyn, College of Physicians and Surgeons, Boston, 1890, joined the U S Public Health Service as an assistant surgeon in 1893, was promoted through the various ranks and retired in 1932 with the title of medical director, served in various posts in the United States, at Antwerp, Belgium, and Calcutta, India, professor of tropical medicine at the Detroit Medical College, 1901-1902 studied bubonic plague in Calcutta, 1903-1904, chief medical officer at Ellis Island from 1925 to 1928 and a director of the North Atlantic district of the Public Health Service from 1928 to 1932, in charge of extra cantonment zone sanitation at Camp Devens, Ayer, Mass, and Camp Dodge, Des Moines, Iowa, during World War I, made reports on drinking water which resulted in the installation of a filtration plant at Washington D C, in 1898, aged 76, died, February 2, of carcinoma of the colon

Franklin Paradise Johnson * Portland, Ore Johns Hopkins University School of Medicine, Baltimore, 1920, assistant clinical professor of urology at the University of Oregon Medical School from 1908 to 1910 Austin teaching fellow at Harvard Medical School Boston, and instructor of histology and embryology from 1910 to 1912, assistant professor of anatomy in 1912, associate professor in 1913 and professor 1919-1920 at the University of Missouri, Columbia, specialist certified by the American Board of Urology, Inc member of the American Urological Association and the American Association of Anatomists, fellow of the American College of Surgeons, received the Ph D degree from Harvard University, Boston, in 1912, collaborator in the writing of a number of medical books, member of the staffs of the Multnomah Hospital and the Good Samaritan Hospital where he died, February 12, of coronary thrombosis, aged 55

John Frank Fraser * New York, Bellevue Hospital Medical College, New York, 1892, specialist certified by the American Board of Dermatology and Syphilology, member of the American Academy of Dermatology and Syphilology, formerly assistant professor of clinical medicine (dermatology), Cornell University Medical College, and associate professor of clinical dermatology and syphilology at the New York Post-Graduate Medical School, Columbia University, served as a major in the medical corps of the U S Army during World War I, an associate attending physician in dermatology, New York Hospital, aged 75, died January 31, in the French Hospital of pulmonary embolism following an appendectomy

Elwood Tracy Easton * Boston, Harvard Medical School, Boston, 1899, specialist certified by the American Board of Ophthalmology, member of the New England Ophthalmological Society, professor emeritus of ophthalmology at the Tufts College Medical School, where he served as professor and instructor of ophthalmology, for some time consulting oculist to the Parental School in West Roxbury, served as consulting surgeon in ophthalmology, ophthalmic surgeon and on the outpatient staff of the Massachusetts Eye and Ear Infirmary, for many years a trustee of the Gordon College and of the Baptist Home of Massachusetts, aged 66, died, January 31, of angina pectoris and arteriosclerosis

Charles Shorey Butler * Boston, Harvard Medical School, Boston, 1898 treasurer of the Massachusetts Medical Society, for many years assistant in anatomy at his alma mater, served for seven years as assistant surgeon in the Massachusetts Volunteer Militia and later as a captain and assistant surgeon in the Eighth Infantry Regiment, was made a Chevalier of the Legion of Honor by the French government for his service in the French Army, lieutenant colonel in the medical reserve corps of the U S Army not on active duty, served during World War I, aged 72, died, February 23, of coronary disease

George Wilder Appleby, Waterloo, Iowa, Chicago Medical College, 1885, aged 82, died, January 22, of coronary occlusion

William Thomas Bailey, Boston, Harvard Medical School, Boston, 1900 member of the Massachusetts Medical Society, past president of the Boston Anesthesia Society aged 73, died, January 16 in the Massachusetts General Hospital, Phillips House, following an operation for carcinoma

Charles Stephen Bartholomew Cassasa * New York, Columbia University College of Physicians and Surgeons, New York, 1912, for many years instructor of pathologic anatomy at the Cornell University Medical College, an assistant medical examiner for the City of New York from 1918 to 1930, surgical director and chairman of the medical board of the Harlem, Lutheran, Mother Cabrini, St Elizabeth and Knickerbocker hospitals, aged 57, died, February 22, of coronary thrombosis

Gilbert de Leverance Forbes * Kendall, N Y, University of Buffalo School of Medicine, 1909, for thirty years health officer of Kendall and school physician at the Kendall High School for twenty-five years, past president of the New York Association of School Physicians, aged 61, died, February 10, of heart disease and hyperthyroidism

Thomas Jonathan Long * Denison, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1902, fellow of the American College of Surgeons, mayor of Denison, formerly president of the Chamber of Commerce, served as chief of staff of the Missouri, Kansas, Texas Railroad Employees' Hospital and the Long-Sneed Clinic Hospital, aged 68, died, January 10, in Whitesboro of angina pectoris

Paul Otto Luedeke, Rochester, N Y, University of Buffalo School of Medicine, 1901, member of the Medical Society of the State of New York, aged 73, died, January 25, of coronary occlusion and arteriosclerosis

Clarence J Stanley, Camp Wood, Texas State University of Iowa College of Medicine, Iowa City, 1902, aged 69, died, January 9, of heart disease

Wilson E Van Loon, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1891, aged 76, died recently in the Presbyterian Hospital of arteriosclerotic cardiovascular renal disease

Frederick George Vogel * Waterloo, Ill, St Louis University School of Medicine, 1906, aged 74, died, January 30 in St Louis

Hugh S White * El Paso, Texas, University College of Medicine, Richmond, 1900, past president of the El Paso County Medical Society, fellow of the American College of Surgeons, served on the board of health of El Paso County for many years and as city and county health officer, member of the staff of the El Paso Masonic Hospital, Hotel Dieu Sisters' Hospital and the Southwestern General Hospital, on the board of the El Paso City-County Hospital, aged 67, died, January 22, of heart disease

DIED WHILE IN MILITARY SERVICE

Arthur Pickens Vandergrift Jr, Memphis, Tenn University of Tennessee College of Medicine, Memphis 1939, member of the Mississippi State Medical Association, served as director of the De Soto County health unit at Hernando, Miss, began active duty as a first lieutenant in the medical corps, Army of the United States and later became a captain aged 28, was killed in an army bomber crash near Columbia, S C, January 27

T Dwight Hunt, Madison, Wis, University of Oregon Medical School, Portland, 1935, member of the State Medical Society of Wisconsin, was called to active duty in September 1942 as a first lieutenant in the medical corps, United States Army Air Corps, aged 35, stationed at Pueblo, Colo, where he was killed in an airplane accident, January 24

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Unlicensed Practice by Chiropractor—The defendant, a chiropractor, was convicted of practicing "chiropractic and medicine" in Virginia without the license required by law and appealed to the Supreme Court of Appeals of Virginia, which reversed and remanded the case (*Grosso v Commonwealth*, 177 Va 830, 13 S E (2d) 285, J A M A 116 2103 [May 3] 1941). He was again tried and convicted and again appealed to the Supreme Court of Appeals of Virginia.

The defendant contended, among other things, that the evidence adduced at the trial was not sufficient to sustain the conviction. It appeared from the evidence that he had rented rooms in an office building and had fitted them out with appropriate appliances. He had a secretary, and he listed himself as a chiropractor in the local telephone book and by publications kept the public advised of his movements. Furthermore, the defendant held himself out as being competent to treat a wide variety of cases, extending from backache to heart disease, and he published testimonials to the effect that he could and did cure disorders which did not yield to conventional treatment. On the basis of this evidence the court held that the verdict was plainly supported.

It was next contended that the trial court erred in admitting evidence tending to show the conduct of the defendant immediately before Dec 11, 1939, which was the date on which it was charged that the chiropractor violated the medical practice act. Of course, said the court, the commonwealth must prove, and it did prove, that he violated the medical practice act. If Dec 11, 1939 had been curtailed off, the jury could not have told what it was all about. When the defendant set himself up in business and held himself out as a chiropractor, without having obtained a license to follow that vocation, his offense was a continuing one. Accordingly, evidence of his conduct immediately prior to Dec 11, 1939 was admissible in evidence.

Finally, it was contended that the defendant and his school of medicine were discriminated against in that chiropractic was not recognized in the medical practice act as a worth while school of the healing art. The chiropractor's approach is wrong, said the court. The chiropractor's real complaint is that no

special provision is made in the medical practice act for him. A chiropractor can be licensed to practice when he meets the requirements of the board of medical examiners. Under the provisions of the medical practice act, an applicant to be licensed must show that he has studied medicine not less than four school years, including four satisfactory courses of at least eight months each in four different calendar years in a medical school registered as maintaining a standard satisfactory to the state board of education. The defendant, it appeared, had graduated from the Palmer School (a full three year course) at which school was taught "a course of anatomy, histology, physiology, embryology, and chemistry." The defendant had not applied to the board of medical examiners for a certificate and with no training other than what he possesses he could not have applied successfully. Statutes designed to preserve the people's health must be very arbitrary to be unconstitutional. New schools must prove their worth to the satisfaction of the legislature before they are recognized. They come and go and "continue not in one stay." It is within wide limits for the legislature to say when their worth has been sufficiently established and what are the tests they must undergo. Certainly, the court concluded, the science of medicine is not static, but society must protect itself against those who are unable or unwilling to undergo that training and to measure up to those requirements now fairly universally recognized. Accordingly the judgment of conviction was affirmed—*Grosso v Commonwealth*, 21 S E (2d) 728 (Va, 1942).

Medical Practice Acts Unlicensed Practice as Violation of Act in Absence of Express Prohibition Against Unlicensed Practice—Miller, a chiropractor, was convicted of unlawfully practicing medicine in Virginia in violation of the medical practice act of that state in that he had not taken and passed the examination which persons who desire to practice medicine in Virginia must take and pass before the Virginia state board of medical examiners. He appealed to the Supreme Court of Appeals of Virginia, contending that no statute in Virginia required him to take and pass an examination before the board of medical examiners as a condition precedent to the practice of medicine.

In passing on the validity of the chiropractor's contention it was necessary for the court to consider the legislative history of the laws regulating the practice of medicine in the state. Briefly, the first medical practice act enacted in Virginia was enacted in 1884 (Acts of Assembly, 1883-84, p 79), and that act contained a specific section (seven) which, in effect, prohibited any person who commenced the practice of medicine after Jan 1, 1883, from practicing for compensation "without first having obtained a certificate" from the board of medical examiners. In 1912 the 1883 act and the amendments thereto were repealed and a completely new medical practice act was adopted. That new act provided for a board of medical examiners to examine and license applicants for licenses to practice medicine. Provision was made for "legal practitioners of medicine practicing under the provisions of previous laws." The board was given authority, in its discretion to arrange for the issuance of licenses by reciprocity. The board was authorized for stated causes to refuse to examine applicants or to revoke or suspend licenses already issued. A section denominated certain classes of persons who were exempt from the provisions of the act under stated circumstances. Licentiate who were graduates of sectarian schools were not permitted to administer drugs or practice surgery unless authorized to do so by the board. The penalty section merely provided that any person practicing medicine in the state in violation of the act should be subjected to a certain penalty. The act was amended from time to time but in no way material for the purposes of the present discussion. In 1942 the legislature filed a bill which would

have amended the medical practice act so as specifically to make it unlawful for any person to engage in the practice of medicine in the state without first having obtained from the board of medical examiners a license or certificate to do so. The gist of the chiropractor's argument was that since the medical practice act of 1912, as amended, did not specifically prohibit practice without complying with the provisions of the act—that is, with respect to a person not entitled to reciprocity or not exempted from the act—without first submitting to and passing an examination by and being licensed by the board of medical examiners, no penalty could be imposed on a person who practices medicine without submitting to and passing an examination and being licensed by the board of medical examiners.

The original medical practice act, said the Supreme Court of Appeals, specifically made it unlawful for a person to commence the practice of medicine or surgery after Jan 1, 1883 for compensation without first having obtained a certificate from the board of medical examiners. Plainly the medical practice act of 1912, which repealed the prior act, was intended to regulate properly the practice of medicine and surgery. The necessity for regulation is made plain by the fact that the act was an emergency act. It was intended to put up bars and not let them down. Conditions under which certificates might be obtained were made more stringent. If the chiropractor's contention is sustained, then the net effect of the 1912 act was to make the suppression of incompetent followers of the healing art impossible. To attribute to that act any such purpose is unthinkable. If the contention of the chiropractor with respect to the 1912 act, as amended, is sound, then any one, at his election, be he snake doctor or magician, can hold himself out as a qualified practitioner of medicine and follow that vocation, all the trouble that the legislature has taken to safeguard the profession and to make an efficient aid to public health is but a futile gesture. As was said by the Supreme Court of Appeals of West Virginia in *Newhart v Pennybacker*, 120 W Va 774, 200 S E 350:

Where a particular construction of statute will result in an absurdity, some other reasonable construction which will not produce the absurdity will be made.

The 1912 statute, which became a law thirty years ago, continued the court, has been everywhere construed as the Commonwealth contends that it should be construed as prohibiting unlicensed practice. That construction which for a long period of time has been accepted by bench and bar as the true construction of a statute becomes a canon of construction, unless some paramount reason is advanced for a change of the conclusion. *St Josephs Soc v Virginia Trust Co* 175 Va 503, 9 S E (2d) 304. Again, the legislature has seen fit to except from the operation of the medical practice act stated types of physicians under stated circumstances. Such physicians are not required to secure certificates from the examining board under the circumstances stated. Such an exception would be wholly unnecessary if no one was obliged to secure a certificate. Again, authority is given the board in its discretion to arrange for reciprocity with the authorities of other states and territories having requirements equal to those established in Virginia. Obviously, no reciprocity would be necessary if anybody could practice medicine in the state. The legislature, continued the court, had occasion to consider this subject at its 1942 session when it had before it the bill previously referred to which specifically proposed to prohibit a person practicing in the state without being licensed to do so by the board of medical examiners. Since it refused to pass that bill, it must be presumed that it was not thought necessary to pass such a measure because the matters dealt with in the bill had theretofore been amply covered by the statute.

For the reasons stated, the judgment of conviction was affirmed—*Miller v Commonwealth*, 21 S E (2d) 721 (Va, 1942).

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fifteenth Annual Meeting held in Chicago No 6 and 7 1942

The President, DR ARLE R BARNES, Mayo Clinic, Rochester, Minn., Presiding

Calcium, Phosphorus and Vitamin D Therapy in Hyperthyroidism

DR ITALO D PUPPEL, DR HAROLD T GROSS, EMMA K MCKORVICK, M Sc, and DR GEORGE M CURTIS, Columbus, Ohio. The calcium balance of 3 normal persons, 7 persons with exophthalmic goiter and 4 with toxic nodular goiter was determined under variations of calcium, phosphorus and vitamin D feeding over a total period of about five hundred days.

The disturbances of calcium metabolism in hyperthyroidism usually consisted principally of an increased excretion of calcium through both the gastrointestinal and the urinary system. The blood calcium and phosphorus usually remained within normal limits. These abnormal findings differ greatly from those in hyperparathyroidism, in which the increased excretion occurs almost quantitatively through the urine while both the blood

calcium and phosphorus levels are usually disturbed. They lead to definite differences in the clinical manifestations of the disturbed calcium metabolism in these two disease entities. In hyperparathyroidism with its usual hypercalcemia and hypophosphatemia metastatic calcification frequently results. Urinary stones occur in about half the cases and constitute one of the most dreaded complications of this disease. In hyperthyroidism, with its usual eucalcemia and euphosphatemia even in the presence of increased calcium excretion equal to or often greater than in hyperparathyroidism, metastatic calcification is rarely observed. Urinary stones occur rarely and are probably only coincidental.

The real danger in feeding high calcium and phosphorus preoperatively in hyperparathyroidism is this increased predisposition to metastatic calcification. In hyperthyroidism there is no such danger, and we have therefore given many of our patients with hyperthyroidism a high calcium, phosphorus and vitamin D diet preoperatively for several years. Not one of these patients has developed the so called thyroid crisis.

The disturbance of calcium metabolism in hyperthyroidism varies greatly. It is usually temporary, preventable and reversible. It can easily be controlled by ingestion or parenteral administration of extra amounts of calcium supplied in various forms such as calcium in milk, calcium gluconate, calcium lactate with a preparation of crystalline vitamin D and calcium phosphate with viosterol by mouth, as well as by calcium chloride intravenously. The disturbance is usually temporary in its effect on bones, but at times and particularly in long standing hyperthyroidism in the presence of insufficient calcium intake permanent bone changes may occur which are not amenable to therapy of any type. Practically this far advanced stage can be treated best by prevention with extra calcium feeding combined with early diagnosis and treatment of the hyperthyroidism.

Administration of extra calcium phosphorus and vitamin D is of particular value in hyperthyroid patients who refuse operation in inoperable cases in patients who are being treated medically or by x-ray therapy, as well as during the preoperative and postoperative management of the usual hyperthyroid patient until the basal metabolic rate returns to normal.

DISCUSSION

DR CECIL STRICKER Cincinnati: Were there any x-ray studies of bone showing deposition of calcium following treatment?

DR HENRY T. RICKALTS Chicago: How low were the low calcium diets and what happened to the hyperthyroidism on a diet of normal calcium content?

DR JOHN TUCKER Cleveland: Was calcium administered to the hyperthyroid patients without giving the usual preoperative doses of iodine? If this was done, did the calcium have any beneficial effects on the symptoms prior to operation?

DR R. D. TAYLOR, Indianapolis: What was the effect of the administration of iodine on the calcium metabolism in hyperthyroidism? Does calcium metabolism directly parallel the basal metabolic rate?

DR ITALO D. PLUPPEL, Columbus, Ohio: Several patients had hyperthyroidism for several years prior to thyroidectomy and calcium therapy and had moderately severe osteoporosis. The evidences by x-ray examination of recalcification after five months of adequate calcium therapy were often not convincing but were present occasionally. It is possible that the degree of calcium loss prior to thyroidectomy was so great that a longer period of time will be required to replace the loss. The relatively low calcium diet which we gave the hyperthyroid patients averaged 520 mg of calcium daily. Our normal controls remained in equilibrium with this amount of calcium. The hyperthyroid patients, however, showed severe loss of calcium. One exophthalmic goiter patient was provided 800 mg of calcium daily, an amount which easily kept normal controls in positive calcium balance. This patient also showed a loss of calcium with a negative balance of 330 mg of calcium daily. Our high calcium diets for the hyperthyroid patients ranged from 1800 to 3,160 mg of calcium daily. These diets permitted them to retain calcium. Calcium therapy does improve the musculoskeletal symptoms. With bed rest, high caloric and

high calcium intake we usually obtained definite improvement in the general symptomatology and a decrease in the basal metabolic rate of hyperthyroidism. However, when iodine was then supplemented, usually there was further amelioration of symptoms and further decrease of the basal metabolic rate. Calcium does have a definite place as replacement therapy in hyperthyroidism. On the other hand, we do not advocate its use in place of iodine. If iodine administration returns the basal metabolic rate of hyperthyroidism to normal, a decrease in the calcium excretion usually occurs. Increased iodine feeding to 1 patient with severe exophthalmic goiter produced no appreciable change in the basal metabolic rate. The loss of calcium by this patient remained as high as previous to iodine medication.

Classification and Treatment of Male Gonadal Failure

DRS CARL G. HELLER, RICHARD M. JOHNSON and GORDON B. MYERS, Detroit: Fifty-one men with sexual impotence and other features of gonadal failure were classified into eight different clinical syndromes on the basis of skeletal development, secondary sex characteristics, urine gonadotropic titer and symptomatology. The series included 16 eunuchs. They were about equally divided between primary pituitary gonadotropic failure and primary testicular failure. Thus, 8 excreted amounts of gonadotropic hormone far below normal levels and 8 excreted amounts above normal levels and equal to estrate excretion. Similarly some instances of adult gonadal failure were associated with low gonadotropic excretion levels and others with estrate (high) excretion levels.

The gonadotropic titer proved to be a reliable therapeutic index. Each patient with pituitary gonadotropic failure responded well to chorionic gonadotropic therapy. No case with initially high pituitary gonadotropic output responded to administered gonadotropins. Both types responded to substitution therapy with testosterone propionate. Since the gonads are still capable of responding at any age (from 15 to 52 years) it is suggested that in lieu of hormone assays a therapeutic trial of chorionic gonadotropins be given all patients with gonadal failure before substitution therapy is resorted to.

Gonadal failure resulted in the androgen withdrawal symptoms of the male climacteric in 18 of 24 adult cases. Sixteen had elevated gonadotropic titers and 2 had diminished titers. Chorionic gonadotropins alleviated climacteric symptoms in the 2 cases due to pituitary failure. Testosterone propionate was effective in 14 of the 16 cases of primary testicular failure. From comparisons with normal men it was concluded that the male climacteric does not occur physiologically and is a definite disease entity.

DISCUSSION

DR M. A. BLANKENHORN Cincinnati: What are your criteria for satisfactory treatment in the hypogonadal eunuchoid type?

DR W. E. BROWN, Omaha: Chorionic gonadotropins in women cause general gonadal atrophy. How was success measured with gonadotropins in men? Also is the therapy not associated with subsequent atrophy such as found in women?

DR DANIEL L. SEXTON, St. Louis: What criteria do you have for a good result in those adults that are given chorionic gonadotropins?

DR CARL G. HELLER, Detroit: There are two treatments for patients with hypogonadism: stimulatory and substitutional. If endocrine studies are not available, the rational approach is to try stimulation first (with gonadotropic hormone). This therapy might produce puberal changes which are maintained. We have had a patient go four months without treatment and maintain sexual potency and secondary sex characteristics. Large doses, 1,500 units of pregnancy urine extract, are used for six weeks. If the gonadotropic hormone treatment fails then substitution therapy with testosterone propionate is begun. The criteria of success consist in increase in size of the penis, increase in sperm count, increase in body hair and a change in the pitch of the voice. The high pitched voice is a definite and serious handicap, it is the reason the patient is discriminated against. We have had difficulty growing beards. It seems that the growth of beard hair occurs slowly, if at all, with any form of therapy. We have taken testicular biopsies after treatment with chorionic gonadotropins and found evidence of stimulation of the testes.

(To be continued)

vein may result from retrograde circulation which is common in the presence of incompetent venous valves. Some of the platelets also may result from the breaking up of agglutinated groups and by passage through dilations that amount to minor arteriovenous anastomoses. I am assuming that the finer capillary beds give a relative index of the damage to the tissues themselves. In a portion of these cases tests were taken from the center of sclerosed areas. These counts corresponded closely to the toe counts.

Since these smallest of blood cells are held back when polymorphonuclears and erythrocytes are able to pass through the smaller capillaries, it is probable that they are retained by adherence and dissolution. Their products and the tissue catabolites, therefore, form the waste that accumulates as the vicious circle revolves. The platelet loss in the capillary areas of the skin may explain the purpuric breakdown of the varicose ulcer.

The method of counting used is reported by the collaborating author.

LABORATORY PROCEDURE

Technic—A drop of freely flowing blood from a deep stab wound, made with a number 11 Bard Parker knife was obtained from the ear and fourth toe of each foot after a thorough cleansing with 50 per cent ethyl alcohol. This blood was drawn to the 0.5 mark of a certified¹⁰ Thoma erythrocyte diluting pipet, immediately diluted with Rees-Ecker¹¹ fluid to the 101 mark and shaken vigorously for thirty seconds. The pipet was labeled, capped with a rubber band and placed in the refrigerator at 4 C, unless counted at once. At the time of the counting the pipet was brought to room temperature, shaken by hand for thirty seconds and then by mechanical shaker for five minutes, and the two sides of a certified,¹⁰ improved Neubauer type hemocytometer were correctly filled. After the hemocytometer had stood (in a Petri dish containing moist filter paper) for a period of fifteen minutes, the number of platelets in the center square millimeter of 400 squares was counted on each side of the hemocytometer and the average of these numbers was multiplied by 2,000, giving the number of blood platelets per cubic millimeter of blood. The normal count is 200,000 to 400,000.

Pipets were cleaned after each count by drawing them full of cleaning solution (commercial sulfuric acid saturated with potassium dichromate) and withdrawing after one hour. A quantity of distilled water was then run through them until no trace of acid remained. They were then rinsed with acetone and dried with air by suction. Hemocytometer surfaces were cleaned with cleaning solution, rinsed with distilled water and wiped dry with a soft lintless cloth.

The diluting fluid of Rees and Ecker¹¹ is prepared by dissolving the following constituents in 100 cc of distilled water and filtering and refiltering weekly: sodium citrate 3.8 Gm, formaldehyde neutral, 40 per cent, 0.2 cc, brilliant cresyl blue 0.1 Gm.

Choice of Technic—The method used is one that the technologist (N. H.) previously adopted and used for clinical blood platelet counts. When this series of counts was started a critical review of methods was made and this method continued on the basis of accuracy, speed and adaptability to this problem and general clinical use.

Use of a direct method was confirmed after consideration of the literature and Tocantins'¹² brief of 116 technics, including that of Olef.¹³ Conclusive evidence presented by Tocantins shows that direct methods are more accurate than indirect methods in experienced hands. Volume per cent methods were not used, as they may be 56 per cent in error.¹⁴ A capillary source of blood was essential, as venipuncture would defeat the purpose of the study. Standard certified pipets and hemocytometers are available and adequate.¹⁵ A magnification of 430 diameters using the high dry objective is best, since it avoids errors of overmagnification and undermagnification when continuous use is made of the fine adjustment of the microscope.

Rees-Ecker diluting fluid met all the necessary criteria since it is isotonic and has an anticoagulant, sodium citrate, a fixative, neutral formaldehyde, to prevent morphologic changes and disintegration of platelets for twenty-four hours, ease of preparation and relative stability without precipitation, and a dye to facilitate counting. The dye may be omitted after some practice or may be added as only 0.05 per cent brilliant cresyl blue. Prewetting of the pipet with diluting fluid by the method of Wright and Kinnicutt¹⁶ was found unnecessary in a series of 10 control counts.

TABLE 4—Correctness of Diagnosis Based on Platelet Counts

Distribution (right or left leg) of disorder correctly indicated by low count	Cases	Per Cent
Distribution not correctly indicated	61	75.4
Normal counts found in	10	16.4
	5	8.2
	76	

Finally our purpose in this series was to obtain comparative blood platelet counts, and since the identical technic was used throughout the relationship of the counts from the various sources is valid, even if the absolute number of platelets would vary with another method.

Checks on Technic—Five clinically normal persons were rechecked first, then 3 with thrombopenic purpura and 3 with thrombocytosis, all values being within expected limits and confirmed by gross correlation with Wright's stained coverslip smears. For the first 41 counts, including the foregoing, two pipets were filled from each source and the two values checked within 10,000 or plus-minus 2.5 per cent. The same check was obtained against three other technologists using this method. During the series repeat counts were made at brief intervals on the same patient and found to fall within the 2.5 per cent variation. Needless to say, all recorded counts checked within 1 per cent on the values obtained from the two sides of the hemocytometer. If the first preparation did not check, another was made.

That the method is accurate and usable is confirmed by the recently published results of 126 preliminary and 1,034 final counts made by Pohle¹⁷ and a technician at the Harvard School of Medicine using the direct method. The same technic is used in New York,¹⁸

10 Certified correct by United States (National) Bureau of Standards.
11 Rees H. M. and Ecker E. E. An Improved Method for Counting Blood Platelets. J. A. M. A. 80: 621 (March 3) 1923.

London¹⁹ and Uppsala,²⁰ with consistent results. That the method is superior to the "true indirect" technic of Olef²¹ is indicated by his own high values and the variable normals²² (328,000 to 1,206,000) of experienced workers using Olef's method. Finally, Tocantins'²³ last comprehensive treatise again confirms use of the direct method, even with cutaneous blood.

GENERAL CONSIDERATIONS

Since the first question to arise is bound to be one of laboratory error, the checks on the method are given by the collaborating author, and I believe them to be adequate. Furthermore, the close correlation of the three diverse counts on normal persons has shown any significant error to be largely absent. The further agreement of the findings with the distribution of the disease signifies that actual changes have taken place. Both of us have repeatedly been able to indicate the extremity having pathologic conditions from the counts made, even though the side was otherwise unknown. I have also in several instances found changes developing on the patient's "good side" when a low count has indicated damage. In 1 case subsequent ulceration developed in an untreated leg having a low count, although the treated one had long been healed.

TABLE 5—Responses of Platelet Counts to Treatment (Ascorbic Acid and Support)

	Before Treatment	Interval	Subsequent Count
1 H D	Ear 175 Right foot 162 Left foot 170	8 weeks	300 275 210
2 D H	Ear 96 Right foot 96 Left foot 91	weeks	191 121 102
3 C H	Ear 144 Right foot 102 Left foot 60	4 weeks	110 165 113
4 I W	Ear 210 Right foot 178 Left foot 56	12 weeks	91 216 119

The low ear counts in many of these cases raises an interesting speculation, and that is "Does platelet loss in a damaged area exceed platelet production in a sufficient amount to depress the normal total count?" If one system continually filters out the platelets from the circulating blood, does the whole circulatory structure suffer?" That this does happen is suggested by the lowered ear counts in long-standing cases.

Another problem is "How low may a platelet count fall before tissue breakdown occurs?" Tocantins²⁴ states "Spontaneous bleeding into the skin and mucous membranes often appears when the platelets in cutaneous blood drop below 50,000 per cubic millimeter and disappears when they return to normal."

Petechial tests have also been done in 2 cases, with positive results relative to the concentration of the platelets. It would be interesting if it could be shown that a local scurvy is responsible for damage to the blood vessels.

Since pathologic conditions were indicated in about 4 out of 5 patients examined by a comparison of regional platelet counts, it may be possible on the basis of a thrombocyte deficit for a physician to predict whether or not injection of varicose veins, surgical intervention or other radical procedure can be done without sloughing or failure of success. Furthermore a degree of prognosis should be possible. I believe that my follow-up of these cases justifies the following statements. If the count does not increase within three to six weeks with supporting measures and administration of ascorbic acid in large doses, the prognosis is poor for complete recovery. If the count shows a progressive fall, the prognosis is bad. I feel that in any instance in which there is a low count in an extremity a surgical or an injection procedure not immediately necessary should not be carried out until the thrombocytes have shown a substantial increase.

THERAPEUTIC PROCEDURE

I have routinely applied full elastoplast (Duke Laboratory) bandages for support of the circulation and have administered 200 mg. of vitamin C (ascorbic acid) a day. A few illustrative responses are shown in table 5. Clinical response has paralleled the improvement in the thrombocyte count.

It is important that I am not misunderstood in my use of ascorbic acid. I have not used it in expectation of stimulating platelet production but possibly to aid in the repair of vascular damage. The improvement in the platelet count probably results from an acceleration of the blood flow which keeps the platelets from adhering to the intima. Thus secondary dissolution is avoided. Furthermore, the drain on the rest of the circulation ceases, since platelets are no longer being lost and an increase in the total count results as production again exceeds destruction.

I am not prepared to say whether the circulatory support or the ascorbic acid is responsible but it is probable that both help. The support permits better maintenance of venous flow and the ascorbic acid may assist in the vessel repair. Roentgen therapy has been used in some cases to assist in the softening of sclerotic areas or help the healing of eczemas. I have used it sparingly but believe that it has a place in treatment if intelligently used.

COMMENT

This study must be considered a clinicophysiology experiment. It points out first that tissues are not all bathed alike in a uniform flow of blood constituents. Second, this flow is altered by the withdrawal or dissolution of blood platelets in long-continued slowing of the blood stream in the extremities. This change not only affects the regional blood itself but ultimately results in the lowering of the total number of circulating platelets. The clinical and physiologic conclusions are still hypothetical but, if used as an approximate index of the degree of a pathologic process, are of some clinical importance.

CONCLUSION

Regional diminution of thrombocytes in the circulating blood of capillaries is found in certain diseases of the extremities. The local diminution often parallels the local clinical conditions, the most important of which probably is the vicious circle of vascular stasis. This diminution probably is an indication of the degree of vascular damage. It should have therapeutic and prognostic significance.

ABSTRACT OF DISCUSSION

DR THEODORE CORNBLEET, Chicago Best showed that there are physical changes, such as of the surface tension, which cause the platelets to stick to injured vessels. Injured surfaces too have increased permeability, permitting, no doubt the smallest formed elements of the blood to escape. It is difficult to show this escape because these elements disintegrate so rapidly. Just what purpose their arrest at the pathologic site serves is not known but it may be to prevent hemorrhage, since the phospholipid content of platelets induces clotting. They seem also to contain a water soluble material, which acts oppositely on the clotting mechanism inhibiting it. The latter substance may prevent clotting in legs whose tissue becomes diseased. The presence of histamine in platelets would further act to increase permeability, though much recent work ascribes to the eosinophils dominance as carriers of histamine in the blood stream. Zon and others have shown that platelets carry histamine in rabbits' blood. In other species examined, including man, the eosinophils have this function. Accurate and reliable platelet determinations cannot be done easily and routinely in office, clinic or hospital practice, and this difficulty limits procedure to only a few with especially trained technicians. Could other tests more easily done substitute without any sacrifice? One which might possibly do so is the determination of sedimentation rates on the blood from the extremities. It would be well to have differential counts made on the same blood samples used for the platelet counts. In leukemia purpura may not be present when high or not too extremely low platelet counts are present. This shows that there are other factors present determining bleeding when it does occur in leukemia, in addition to the mere number and quality of platelets. Dr Maynard has charted a most interesting point to be used with other ones yet to be found to form a line pointing beyond academic interest to clinically useful information.

DR MERLIN T R MAYNARD, San Jose, Calif. I thank Dr Cornbleet for raising all these questions. I have thought of every one of them. Being a clinician, I hope that somebody with more laboratory time than I have will be able to dig into this side of it. I have always had the one technician do every count and she has been accurate. We can recheck the same individual over and over again and get the count within a very small margin of error. That has all been done on the laboratory side. Tourniquet tests? Yes, I would like to do them, and I would like to get some purpuras. I have done intracutaneous vitamin C tests, but they have not been very successful. The dye seems to be dispersed almost as rapidly in the pathologic areas as in the normal skin. I would like to see sedimentation rates done. The capillary microscope too. I did some of that work many years ago and I haven't thought of it in this case. We have done the differential counts and the interesting thing is that we get perfectly normal white cell and red cell counts, but the platelets are deficient. The platelets are the only ones that are severely interfered with in their distribution.

Skin Grafts—The skin graft was first used in 1847 by the American surgeon F H Hamilton. In 1869, two years after he had demonstrated the parasitic properties of skin, Reverdin of Geneva introduced the so called malpighian graft, 2 to 6 mm in size. The technic of skin grafting was improved by Karl Thiersch of Munich, professor of surgery in Erlangen, who in 1874 described the method which has since been known by his name but with which Ollier's name should also be associated for this great French orthopedic surgeon had already described a method exactly similar in 1872. The 'pinch' graft, consisting of a small conical graft of skin about half a centimeter in diameter, is generally attributed to Staige Davis (1919). More recently the grafting of small pieces of skin was greatly improved by my own teacher Manuel Corachan, who in 1933 published an account of the technic with which he had obtained highly successful results. Since 1917 the chief exponent of the whole thickness living graft in the form of tubed pedicle flaps has been Sir Harold Gillies, to whose school the progress of modern plastic surgery has been so largely due—Trueta, Joseph. *The Principles and Practice of War Surgery*, St Louis, C V Mosby Company, 1943.

IRRADIATION OF THE SPLEEN AND
PITUITARY FOR CONTROL OF
PUBERAL BLEEDINGBIRTH OF A NORMAL CHILD FOLLOWING
TREATMENT OF THE MOTHERIRA I KAPLAN, MD
NEW YORK

An entirely unwarranted fear that irradiation may do harm to the generative organs is one of the main reasons why this well tested method is not more generally utilized in the treatment of irregular bleedings in young girls. While it is true as Halberstaedter¹ reported early after the advent of x-rays, that these exercise a selective action on the ovaries nevertheless, when roentgen therapy is properly employed, permanent suppression of ovarian function and damage rarely occur.

In 1939 I² reported the case of a young woman who, intensely irradiated over the pelvic area at 4 years of age, nonetheless menstruated at 12 years and now, at the age of 17½ years, continues to have regular periods. Commenting on this case, Dr George L. Streeter³ of the Carnegie Institute of Embryology states:

"I believe the factor involved in your case is the principle that the more primordial the cells the more resistant they are to x-rays, whereas ova in the later stages of their differentiation are easily destroyed by x-rays, and the primordial cells which will produce their successors are perhaps not so easily affected. In your case the heavy treatment that the patient received certainly killed off all the follicles but in the course of time the primordial ovarian tissue produced a new crop of eggs along with their accessory cells and this finally resulted in the resumption of menstruation."

It has been our experience⁴ that the younger the woman treated for sterilization the less permanent is the menstrual suppression. It would appear as Streeter states that, while destruction of follicles does occur, primordial cells in the course of time develop new follicles and normal menstruation takes place. This evidently occurred in a case I⁶ reported in 1930 in which after a total sterilizing dose of x-rays, the patient resumed normal menstruation and subsequently gave birth to a normal child.

From my experience irradiation of young women and girls may be employed for gynecologic dyscrasias provided the dosage and method are properly selected. Not always is irradiation required directly over the ovaries. Beclere⁵ was one of the first to demonstrate that irradiation of the pituitary may have an effect on menstruation. Since it has been established that the pituitary plays an important role in regulating the menstrual function under normal conditions roentgen therapy has been applied to this area in an attempt to control menstrual disorders, thereby avoiding direct action on the ovaries. This method is especially effective in some cases of dysmenorrhea. In 1929 Ford and Drips⁷ reported definite relief of menstrual irregulari-

ties from roentgen irradiation of the pituitary along with irradiation of the spleen

Definite information about the spleen function is still lacking, but, owing to the relationship between the spleen and the blood vascular system and thrombopenic purpura, splenic irradiation has been used for the control of various types of hemorrhages, especially those associated with ovarian or uterine origin. The effect is not entirely due to increasing coagulation nor does irradiation of the spleen produce a specific coagulation effect. Action through the lymphocytes is probable.

In 1923 Nurnberger⁸ reported on the favorable results of irradiation to the spleen in internal hemorrhages and believed it due to the indirect effect on the ovaries and an increase of the blood coagulability. Borak⁹ in 1924 recommended splenic irradiation for refractory gynecologic bleeding and suggested that the response was due to x-ray reaction on the nuclear substance, which produced a styptic effect. Seitz¹⁰ reported the hemostatic effect of splenic irradiation in uterine bleeding. Martius¹¹ reported irradiation of the spleen not only effective in juvenile uterine hemorrhage but also effective in 75 per cent of the cases of bleeding due to ovarian conditions. Werner¹² found that hemorrhage at puberty was quite amenable to irradiation of the spleen and that 70 per cent of the cases responded to a single treatment. He believed that the effect was due to temporary disturbance of the control mechanism. He also noted the favorable effect of pituitary irradiation for such conditions.

Treatment over the spleen can be administered without much hazard of affecting the ovaries, the indirect effect on the ovaries being considerably less than the supposed damage resulting from direct ovarian irradiation in young women and girls. In menorrhagia at puberty or just beyond this period, roentgen therapy to the spleen and on the pituitary can be safely administered without interfering with subsequent ability to bear children.

The following case is an illustration of this sequence.

F. R. (now F. R. C.), a young Jewish girl aged 14½, was referred to me on Nov. 17, 1931 with a note from her physician stating that she started her menstrual history in January of that year. Her first two periods were characterized by slight staining and the last three or four periods were marked by profuse hemorrhages lasting for seven days or more followed by irregular staining.

She was kept in bed for several weeks and treated with various glandular medicaments without avail, also injections were given to raise the blood calcium, and as a last resort she was referred for roentgen therapy.

She was one of three children. The mother's menstrual history was normal. The patient as a child was frequently ill and at 4 suffered from chorea. She looked pale although her blood examination showed only a mild anemia.

The patient was thin, pale and nervous. No vaginal examination was done. The abdomen was soft and no masses were felt. The spleen was not palpable. Rectally there was no pelvic abnormality discernible.

It was decided to institute roentgen treatments to forestall further bleeding. High voltage roentgen therapy was administered over the splenic area, the rest of the pelvis where the ovaries lay was not covered. The factors used were 180 kilovolts, 5 milliamperes, 0.5 mm. of copper and 2 mm. of aluminum filter, at 30 cm. distance through a 6 by 8 cm. port. An 18 per cent skin erythema dose was given (the roentgen measurement was not employed at that time).

On Dec. 11, 1931 she reported that menstruation had started on November 20, lasted but five days and was not so profuse as the previous one. Although she was requested to continue further treatments, the patient did not report again until Jan. 6, 1932, when she stated that, following the November 1931 menstruation she did not bleed again for two months, after which menstruation was irregular until August 1932 when she bled for three weeks into September 1932. In October menstruation lasted four days. The following period was delayed till Dec. 25, 1932 when she started to bleed and was still bleeding profusely on Jan. 6, 1933, when she again reported to me for treatment. This was administered with a 20 per cent dose to the spleen and a 15 per cent dose to the pituitary area. I advised further treatment because it was felt that the single small dose would not be sufficient to give sustained control of the irregularity. However the patient was not seen again until Sept. 20, 1933 when she reported having menstruated irregularly about every two months until September 5 when profuse bleeding started. She was treated with a 20 per cent dose of x-rays to the spleen and, as before, failed to return again until June 27, 1934, when she did so only because she had had continuous bleeding since June 17, 1934. A dose of 15 per cent roentgen therapy was given to the spleen and pituitary areas. Normal menstrual periods followed in July and August. On Nov. 2, 1934 severe bleeding started and on November 15 roentgen treatment was administered to the spleen (20 per cent dose) and to the pituitary (15 per cent dose). Normal menstruation followed until January 1935.

Severe bleeding appeared on Feb. 16, 1935. On March 13 a dose of 15 per cent was administered to the spleen and pituitary areas. Normal menstruation followed in April and May. In June there was no menstruation, on July 13 she began to bleed and continued until Aug. 2, 1935, when treatment was again given in 15 per cent doses to the spleen and pituitary areas. Bleeding lasted for ten days and then stopped. She then menstruated regularly for five to eight days until July 8, 1936 when bleeding was prolonged. On July 20, 1936 80 roentgens was given to the spleen. Regular periods followed until August 1937. On Aug. 10, 1937 70 roentgens was given to the spleen with partial control of bleeding. On August 28 sudden hemorrhage occurred and continued until Sept. 21, 1937, when treatment was given to the spleen and pituitary areas, a dose of 150 roentgens and 75 roentgens administered to each area respectively. Bleeding stopped the next day.

Following this last treatment normal menstruation was established lasting two to three days and continued regularly thereafter. In September 1939, at the age of 22 she married and regular menstruation continued. In May 27, 1941 she reported having skipped two menstrual periods and examination revealed a pregnancy. She carried this normally and on Feb. 6, 1942 was delivered of a normal, full term baby girl.

COMMENT

Since x-rays are known to have a selective action on the ovaries, the use of this modality in the treatment for irregular bleeding in young girls has been deemed inadvisable and other areas to be irradiated were sought for controlling puberal bleeding. However, even though in some instances radiation must be administered directly to the ovaries, seldom is sterilization in young women permanent and whereas ovaries in the later stages of their differentiation are readily destroyed by irradiation, the primordial cells which will produce subsequent ovaries are not affected. The ovary will develop later and, when impregnated, produce normal children.

Because of the recognized controlling influence of the spleen in hemorrhage, roentgen therapy to the spleen has been employed with good results in gynecologic bleedings. The pituitary too is definitely related to the reproductive organs and has been shown to have a pronounced influence on menstrual function. Irradiation of the pituitary has been found to affect favorably gynecologic dyscrasias. Treatment of the spleen and pituitary offers a readily available and effective method

for treating puberal bleeding without direct irradiation of the ovaries, thus removing any fear of possibly adverse effect on the result of future pregnancy

SUMMARY

A young woman, suffering from irregular menstrual bleeding and hemorrhage for nine years, previously having been treated with medication without response, was moderately controlled by roentgen therapy to the spleen and pituitary and eventually resumed normal menstruation. She married at 22½ years and gave birth to a perfectly normal child about two years later. Roentgen therapy, while controlling the uterine bleeding, has no injurious effect on the reproductive organs of the mother or on the child.

While I have treated a considerable number of girls for puberal bleeding, this case has been singled out for a detailed report because it is the first in the series in which the patient has married and borne children, thereby substantiating the repeatedly voiced opinion that roentgen therapy when properly administered will control abnormal puberal bleeding and leave no injurious effect either on the reproductive organs of the mother or on her children.

755 Park Avenue

ABSTRACT OF DISCUSSION

DR RICHARD W. TELINDE, Baltimore. In the last five years in no instance have I used irradiation for the treatment of functional bleeding in women under 35 years of age. I believe it practically never is necessary and the likelihood of the menopause cannot be predicted with certainty. Women are variable in their susceptibility and even with carefully regulated small doses intended to produce temporary amenorrhea I have seen some very tragic permanent amenorrheas in young women irradiated by excellent radiologists. I can't agree with Dr Kaplan when he speaks of supposed damage of x-rays to the ovary. It is not a supposition, it is real. We can see the histologic changes under the microscope and we can follow our cases clinically and see amenorrhea of varying lengths of time with distressing menopausal symptoms.

DR JOHN T. MURPHY, Toledo, Ohio. With regard to the pituitary irradiation of Dr Kaplan, my experience has been that we are able, at least in the majority of cases, at the first treatment to control for varying periods of time the menstrual cycle. However, I have also had the experience of recurrent bleeding in which irradiation was not effective. There again it may be that we don't know the proper dosage to use, and I feel that that may be an answer to that.

DR WILLARD M. ALLEN, St. Louis. I have been much interested in Dr Kaplan's results from irradiation of the pituitary. He had recurrences in his patients the same as in these cases which I have followed. This indicates a fundamental defect in these particular patients in the pituitary relationship.

DR IRA I. KAPLAN, New York. The question of the advantage and disadvantage of treating young women with x-rays has been gone over completely during the last number of years, and we haven't made any definite decision as to what was what. As yet nobody has been able to produce for observation the second or third generation of human beings from people with hormone dyscrasias who have been irradiated. I have a large series of amenorrhea and sterility cases and a large number of children who have been born from these women who have been stimulated, as we call it, by x-rays to the ovary and the pituitary. We are not sure what the pituitary function is. We know it has a definite relation to ovarian function or menstrual function, or even the birth function in the female. It is too soon to state definitely what the after generation of human beings will show, but we can say that so far none of these children show abnormal effects. The oldest child is a boy normally well developed. Boys don't marry as young as girls, so we can't tell much about them except from the anatomic standpoint. The oldest girl I have in my series is

now about 15. She is menstruating normally. I have a group of them now that are commencing menstruation and they are menstruating normally. This is the first generation of the irradiated mother. I can show a girl who at 4½ had a sarcoma of the pelvis, who was one of the fortunate ones that survived. She had intensive irradiation with complete disregard of any ovarian protection. It was to save her life and keep her going because the parents wanted her to live. She had radium and x-rays. She had radium in the rectum, she had x-rays through the pelvis, two intensive courses, enough to warrant a first degree burn of the skin. Now at 17½ she is menstruating normally. One thing about our work in radiation has been left out in all these discussions. No gynecologist ever sends a patient to a radiation therapist unless he has exhausted everything else in the way of treatment and so in every one of the cases that we have reported treatment has been administered by everything else that is known. Irradiation properly given, should not be looked on as a death dealing ray, as something one should avoid.

DR CONRAD G. COLLINS, New Orleans. It is gratifying to find that in relatively few cases, let's say, of puberty or puberal bleeding do we need to use surgery or irradiation, and it can be adequately controlled by endocrine measures in a large number of cases, but perhaps some of the gains made in that area have been lost at the menopause when too much endocrine therapy has been used in an attempt to control bleeding where it may do good temporarily but where the diagnosis is not made correctly, where a few cases of carcinoma are overlooked, where the results are not permanent, and here at this age of life surgery primarily, irradiation secondly, are indicated.

THE DURATION OF PASSIVE TETANUS IMMUNITY

AND ITS EFFECT ON ACTIVE IMMUNIZATION
WITH TETANUS TOXOID

JEAN V. COOKE, M.D.

ST. LOUIS

AND

F. G. JONES

INDIANAPOLIS

In the treatment and prophylaxis of tetanus there are several questions of considerable clinical importance for which there are insufficient data to warrant definite answers. Among these may be mentioned:

1. What is the duration of antitoxic immunity after the usual therapeutic dose of tetanus antitoxin?

2. Does any stimulation of antitoxin accompany an attack of clinical tetanus?

3. Can an active antitoxic immunity against tetanus be produced by repeated subcutaneous or intracutaneous injections of toxoid with sufficient rapidity so that such a method could be used as a prophylaxis for wounds?

4. Does the presence of heterologous antitoxin from passive immunization interfere with active immunization against tetanus by toxoid?

5. Has Ramon's "simultaneous serovaccination" against tetanus any merit?

In this paper we wish to report observations on the immunization of children with clinical tetanus and of normal children which give information on these questions.

MATERIAL AND METHODS

The observations here reported include more than four hundred tetanus antitoxin titrations made on 9 children with clinical tetanus treated in the St. Louis

From the Department of Pediatrics, Washington University School of Medicine, the St. Louis Children's Hospital and the Shriner's Hospital for Crippled Children, St. Louis, and the Lilly Research Laboratories, Indianapolis.

Children's Hospital and on 30 children, aged 8 to 15 years, in the Shriner's Hospital for Crippled Children who were in good health and under orthopedic treatment for various deformities. Permission to carry out experimental tetanus immunizations on the latter was given by the chief of staff, Dr C H Crego. The antitoxin determinations were done under the direction of one of us (F G J) and expressed as American units. The titers given represent minimal values in units per cubic centimeter, since the titrations were done at the following levels: 50, 30, 20, 10, 7.5, 5, 2, 1, 0.5, 0.2, 0.1, 0.05, 0.02, 0.017, 0.01 and 0.003 units. A reading of 0.2 would mean, for example, more than 0.2 unit and less than 0.5 unit. Less than 0.003 unit is tabulated as 0.

In the first series of experimental immunizations (table 3) in which toxoid was injected subcutaneously and intracutaneously plain (fluid) rather than alum precipitated toxoid was used, since it was considered that a more rapid absorption of the antigen might make the observations more definite than the prolonged and lingering action of the insoluble alum precipitated toxoid. The intracutaneous injection of 0.5 cc produced no special discomfort.

In the later series on experimental "simultaneous" and delayed immunization (table 4) with toxoid, the insoluble alum precipitated form was used because it was considered desirable to have a more prolonged and continuous action.

For simplicity in presentation, the results will be given in tabular form, and condensed protocols of the observations on the patients with tetanus will be appended at the end of the paper.

THE DURATION OF PASSIVE ANTITOXIC IMMUNITY

Passive immunization with tetanus antitoxin is generally believed to be of short duration. For example in standard works on immunology Zinsser¹ states "In ordinary human cases, the antitoxin injected into man may be expected to disappear from the circulation within about three weeks," and Topley and Wilson, "Passive immunity conferred by a single injection of (tetanus) antitoxin wears off in about a fortnight or three weeks." In support of such statements are quoted the observations of Glenny and Hopkins,² in which 3 rabbits were given 0.5 cc (375 units) of diphtheria antitoxin and an initial value of 6 to 11 units of antitoxin per cubic centimeter in the blood was reduced to 0 in eleven to sixteen days and of Smith,³ who reported that after the subcutaneous injection of 9,000 units of diphtheria antitoxin a man showed 1.13 units on the 4th day, 0.08 unit on the 20th day and none on the 27th day after the injection. From clinical observation also it has been noted that diphtheria or tetanus may occasionally develop two to three weeks after a prophylactic antitoxin injection of 500 to 1,500 units has been given. Recently Bigler and Werner⁴ carried out antitoxin titrations on the blood of 64 children aged 3 to 10 years at varying times after the

injection of 1,500 units of tetanus antitoxin. They found a wide variation in antitoxin titers in different children and found that some responded less well than others. During the 3d week the tendency was for the level to fall to 0.01 unit, although some remained as high as 0.1 unit and others fell to 0.003 unit or less. In those cases in which there is a more rapid disappearance of passive immunity, the possibility of a previous injection of serum should be kept in mind since under such circumstances the injected serum is destroyed more quickly, as shown by Siquepce and Jude,⁵ who made a similar study on adults after passive prophylaxis with 3,000 (international) units of tetanus antitoxin. There seems little question that with such relatively small doses of antitoxin passive immunity is of short duration. On the other hand when larger doses of antitoxin are given, there is evidence that, although the early high titers fall within a short period, lower levels of antitoxin may persist in the blood for a much longer time.

Actual titrations of antitoxin levels in man after passive tetanus immunization with large doses of antitoxin in clinical tetanus are relatively few, although Decker⁶ demonstrated tetanus antitoxin (amount not stated) twenty-three and thirty-nine days after the intravenous injection of 30,000 units and Cole and Spooner⁷ made observations on 4 patients each given 200,000 units of tetanus antitoxin and in all instances found 10 units after seven days, 3 to 5 units after fourteen days and in 3 cases 1 to 3 units after one month while the fourth patient had 0.33 unit on the 22d day and more than 0.1 unit on the 41st and 63d day. Ramon and his associates⁸ have reported antitoxin titers on 2 adults each given 150,000 (international) units of tetanus antitoxin. (The international unit is half the strength of the American unit.) In 1 of these a titer of 0.1 unit was found on the 49th day and 0.03 unit on the 70th day, while in the other at least 0.1 unit persisted for thirty-seven days and 0.03 unit for forty-nine days. Two other adults who had had serum injections some time previously were also observed after the injection of 150,000 units of tetanus antitoxin. In these the antitoxin disappeared much more rapidly and 0.01 to 0.1 unit persisted for only twenty-eight days. The more rapid disappearance of antitoxin in animals and persons who have had previous serum injections is the rule and to be expected. Solner and Jude⁹ followed the antitoxin in a patient who received 1254,000 units of tetanus antitoxin over a period of eleven days and reported 1 unit present after thirty-nine days, and 0.01 unit was found on the 86th and again on the 106th day after the last antitoxin injection.

The actual level of antitoxin in the blood required to produce clinical immunity to tetanus has not been definitely established, but there is conclusive evidence that higher values are necessary in passively immunized animals than in those actively immunized. The evidence for this conclusion from animal experiments will

be published in detail by one of us (F G J) in a future paper. From our present knowledge it would appear a valid assumption that in human beings clinical protection from tetanus requires a titer of 0.01 to 0.1 unit of passively introduced antitoxin while an active immunity of 0.001 to 0.01 unit is sufficient.

PASSIVE IMMUNITY AFTER LARGE DOSES OF ANTITOXIN

In table 1 are shown tetanus antitoxin titrations on 8 children who were given 100,000 units or more in the treatment of clinical tetanus and in whom the rate of disappearance of the passive immunity was followed for a number of weeks. With these larger doses there was remarkable constancy in the rate of decrease in antitoxin, although in those given more than 100,000 units (cases 1 and 2) there was a higher early level and a somewhat longer persistence of the passive immunity. It will be noted that, while the high initial titers fall quickly, as much as 1 unit remained from three to four weeks after the injection, 0.1 unit from six to ten weeks and 0.01 unit from eight to eleven weeks. In the single observation after 150,000 units was given, the antitoxin persisted longer than in the others after 100,000 units. In case 2 also the concentration of

0.01 unit remains for eight to ten weeks. It was observed in 1 case also that even with a blood antitoxin titer of 30 to 50 units the spinal fluid contained only 0.2 unit, and another patient showed 0.017 unit in the spinal fluid at a time when the blood contained 70 units. In this connection it is of interest that Sohler and Jude¹⁰ found only 0.03 to 0.1 unit per cubic centimeter in the spinal fluid of their patient at a time that the blood showed 50 to 100 (international) units, in spite of the fact that 50,000 units had been injected intrathecally sixteen hours previously.

THE ABSENCE OF ANY ANTITOXIN STIMULATION BY AN ATTACK OF CLINICAL TETANUS

It has long been recognized that tetanus infection does not produce a permanent antitoxic immunity, since a demonstrable antitoxin does not persist in the blood after recovery. The usual explanation is that tetanus toxin is so potent that the absorption of an amount sufficient to produce clinical symptoms is too minute a quantity of antigen to stimulate the production of antitoxin. However, it might be possible for sufficient antigen to be absorbed to produce a primary antigenic stimulus such as occurs after an initial dose of toxoid and which sensitizes the cells to a later, more effective

antitoxin in the spinal fluid was determined on two occasions. On the 3d day the blood showed 50 units, and on the 9th day the blood titer was 30 units, and on both these occasions the spinal fluid had a titer of 0.2 unit per cubic centimeter. Another patient (case 7) had only 0.017 unit in the spinal fluid when the blood titer was 70 units.

When only moderately large doses of antitoxin were given (10,000 units) the duration of a more prolonged passive immunity was somewhat less constant than after 100,000 units or more. In table 2 are collected observations on 21 children after receiving 10,000 units, and the duration of titers as high as 0.1 unit and 0.01 unit is shown. These are summarized from data in tables 3 and 4, which will be mentioned later. It will be noted that in 14 of the 21 children a titer of 0.1 unit persisted for from four to six weeks and a titer of 0.01 unit from six to ten weeks. None of these had had a previous serum injection, while of the 7 subjects whose antitoxin disappeared more rapidly only 2 had had horse serum previously. One other child, a girl aged 14 years, was of special interest, since she showed less than 0.003 unit when tested only two weeks after receiving 10,000 units intramuscularly. Careful inquiry elicited no history of a previous serum injection.

To summarize these observations, it was found that after the injection of 10,000 to 150,000 units the tendency is for tetanus antitoxin to persist in the blood in a titer of 0.1 unit for four to eight weeks, and

secondary stimulus. This could be determined by a toxoid injection after recovery from tetanus. In all, we have made observations on 4 children with clinical tetanus, and none showed any development of tetanus antitoxin when toxoid was given some time after recovery. Two of these (table 1, cases 2 and 3) already mentioned received toxoid injections during the first week of observation, and neither responded

TABLE 2—*Duration of Titers of 0.1 and 0.01 Unit of Tetanus Antitoxin in the Serum of Twenty-One Children After the Injection of 10 000 Units Intramuscularly*

by a rapid development of antitoxin when given a stimulating dose of toxoid two and one-half to three and one-half months later. A third (case 4) had 100,000 units of tetanus antitoxin, all of which had disappeared from the blood in four months, at which time a subcutaneous injection of 1 cc of toxoid was given, but no antitoxin had developed two months later. One child (case 5) had typical but mild tetanus of two weeks' duration when first seen. He was given no antitoxin and recovered within two weeks, without

the developing of any demonstrable antitoxin in the blood. About seven weeks after the first symptoms, a subcutaneous injection of 1 cc of toxoid was given, but no antitoxin developed during the following nine weeks.

These observations confirm the prevailing belief that immunity to tetanus does not follow an attack of the disease and in addition indicate that the amount of tetanus toxin antigen absorbed is so small as to produce no primary stimulus or sensitization to tetanus immunization.

THE POSSIBILITY OF RAPID DEVELOPMENT OF ACTIVE TETANUS IMMUNITY FOR PROPHYLAXIS

The use of toxoid immunization for prophylaxis after wounds has never been seriously considered by immunologists as a substitute for passive immunization with antitoxin, because the time required for the development of active immunity is considerably longer than the incubation period of tetanus. However, the question is sometimes raised by clinicians whether by repeated intracutaneous toxoid immunization a more rapid production of antitoxin could be stimulated. In the group of 4 children (group 3, table 3) observed after the intradermal injection of 1 cc of tetanus toxoid every 2d day until four doses had been given it was found that the blood titer of antitoxin remained below 0.003 unit for the following seven weeks. Another group (group 1, table 3) immunized by subcutaneous injection of toxoid showed a similar lack of antitoxin production. There is no evidence from these observations that either repeated subcutaneous or intracutaneous injections of tetanus toxoid stimulate a more rapid development of antitoxin.

THE EFFECT OF PASSIVE IMMUNITY ON ACTIVE IMMUNIZATION WITH TETANUS TOXOID

The early observations of Glenny and Sudmerson¹¹ on immunization of guinea pigs against diphtheria with toxin or toxin-antitoxin showed that an animal slightly immunized by a previous dose of antigen responds promptly to a second later injection by a rapid production of antitoxin, but if passively immunized with antitoxin when the first antigen was given a later antigen injection stimulates no secondary type of response and in fact no antitoxin may be produced at all. This principle of the inhibition of active immunization by the presence of passive immunity has been rather generally accepted, and it is only in recent years that reports, chiefly by Ramon¹² and his associates, have advocated combining active and passive immunization by the simultaneous injection of antitoxin and toxoid in diphtheria and tetanus. This consists of an initial injection of antitoxin and one of toxoid followed after an interval by a second toxoid injection and preferably later a third dose of toxoid.

The previous work along this line especially with diphtheria, has been summarized and reviewed in a recent paper by Downie and his associates,¹³ who made an extensive series of observations on the combined active and passive immunization of 300 young adults against diphtheria. They conclude from the papers

reviewed and from their own work that the simultaneous administration of antitoxic serum with the first dose of toxoid interferes somewhat with the primary response of the tissues but does not destroy it. Although there may be some delay and slight degree of inhibition in the formation of antitoxin, the final degree of immunity following a later dose of toxoid does not appear to be much inferior to that resulting from active immunization alone. A similar interference with the development of active immunity against tetanus by antitoxin was found by Otten and Hennemann.¹⁴

Many workers have concluded that only free toxoid can produce the primary sensitization of tissues for an active immunity response to a later injection and that if an excess of antitoxin is present the neutralized toxoid has little sensitizing effect. In this connection two considerations are of some importance: (1) the fact that small doses of antitoxin persist in the body for a much shorter time than large doses as discussed previously, and (2) the fact that, although plain (fluid) toxoid when injected is either immediately neutralized by any antitoxin present or combines rapidly with tissue cells to sensitize them, alum precipitated toxoid is insoluble and remains for some days or weeks at the site of injection and only as the insoluble precipitate goes slowly into solution does the toxoid gradually become available either for neutralizing antitoxin or for sensitizing tissues. In almost all the experimental observations the dose of antitoxin has been 1,500 units or less, and in some of them especially the later ones, alum precipitated toxoid has been used. It is apparent that the inhibiting effect of antitoxin on the sensitizing action of early injections of toxoid might be more certainly observed by the use of a moderately large dose of antitoxin and plain toxoid, since alum precipitated toxin presumably has a more continuous and prolonged absorption.

Our first observations on combined immunization were carried out on 18 healthy children and are summarized in table 3, in which is shown a comparison of the effect of toxoid alone with serovaccination by making weekly titrations of tetanus antitoxin in the blood.

In group 1 each of 4 children received 1 cc of plain (fluid) tetanus toxoid subcutaneously every 2d day until four doses had been given, and eight weeks later a single subcutaneous dose of 1 cc of toxoid. As will be noted, no tetanus antitoxin was detectable in the blood following the first series of injections but appeared quickly after the stimulating dose given eight weeks later.

In group 2 the same procedure was followed except that each of the 4 children received 10,000 units of tetanus antitoxin on the first day on which toxoid was given. There was a progressive decrease in (passive) antitoxin titer, and in 1 child (case 3) who had had a previous serum injection the antitoxin had disappeared entirely at the end of five weeks. In none did the toxoid given after eight weeks stimulate the production of any antitoxin within a period of two weeks.

Groups 3 and 4 were identical with groups 1 and 2 except that in them the initial series of toxoid injections was given intracutaneously. The results were the same in that no antitoxin appeared after the later

stimulating dose of toxoid in the children who had received a dose of antitoxin at the outset, although those to whom antitoxin had not been given responded promptly in the usual manner by the development of an active immunity.

The results of these experiments were clearcut and definite. They show that the presence of any considerable quantity of injected antitoxin prevented the primary sensitization or "primary response" of the body cells by doses of toxoid injected during the 1st week, so that a later single dose of toxoid was ineffective in stimulating active antitoxin production.

Further observations on the inhibiting effect of antitoxin on immunization by alum precipitated tetanus toxoid were made on 2 children with clinical tetanus treated with antitoxin and given toxoid simultaneously. Brief protocols of these 2 cases (2 and 3) are given later.

The second child (case 3), a girl aged 10 years was given 50,000 units of tetanus antitoxin on the first day of observation and the same amount on the following day. Alum precipitated tetanus toxoid (0.5 cc) was given intracutaneously on the first day and on each of the following six days. In table 1 are given the blood antitoxin titers, which fell to 0.017 unit on the 76th day. On the 111th day less than 0.003 unit was found, and at this time 1 cc of alum precipitated tetanus toxoid was given subcutaneously. One week later the blood still showed no antitoxin, although four weeks after the toxoid injection (141st day) the serum titer was 0.2 unit, which had decreased to 0.05 unit after five and one-half months. At this time a final dose of 1 cc of plain tetanus toxoid subcutaneously was followed by a titer of 2 units after one week and 5 units after two weeks. In this case the early injections of toxoid apparently produced no primary sensitization, since a

* 1 cc of fluid tetanus toxoid subcutaneously † 10,000 units of tetanus antitoxin intramuscularly
† 1 cc of fluid tetanus toxoid intracutaneously (2 areas 0.5 cc each)

The first child (case 2), a girl aged 8 years, was given 100,000 units of tetanus antitoxin the first day of observation and 50,000 units two days later. Alum precipitated tetanus toxoid (0.5 cc) was injected subcutaneously the first day and on each of the succeeding six days. Determinations of tetanus antitoxin in the blood (table 1) showed a decreasing titer, until on the 68th day 0.1 unit was present. Six days later (74th day) 1 cc of alum precipitated toxoid was given subcutaneously, but the antitoxin continued to fall to 0.017 unit on the 80th day and to 0.003 unit on the 125th day. This indicated that the sensitizing effect of early doses of alum precipitated toxoid had been prevented by antitoxin. On the 125th day 0.5 cc of alum precipitated tetanus toxoid was given subcutaneously with the development of 0.5 unit antitoxin two months later (177th day), at which time an additional subcutaneous injection of 0.5 cc of alum precipitated toxoid resulted in an antitoxin titer of 5 units two weeks later (185th day).

stimulating dose of toxoid three and one-half months later resulted only in the type of response often seen from the first antigen injection. The rapid stimulation of the typical "secondary" response followed a later dose of toxoid.

The observations on these 2 children show that the presence of heterologous tetanus antitoxin inhibited the sensitizing effect of alum precipitated tetanus toxoid given subcutaneously or intracutaneously daily during the first week of such passive immunity, so that a later injection of toxoid did not stimulate antitoxin formation in the prompt manner to be expected from a secondary response.

DEVELOPMENT OF ACTIVE IMMUNITY IN PASSIVELY IMMUNIZED PERSONS

In spite of the inhibition of (passive) antitoxin immunity on the sensitizing effect of early administration of toxoid, it is apparently possible to overcome this inhibition by repeated toxoid injections so that

a state of passive immunization can pass into one of active immunity. This appears to be more readily accomplished when small amounts of antitoxin are given than after large doses. Sacquepée and Jude,¹ for example, treated 240 wounded soldiers prophylactically for tetanus by giving 1.5 cc of anatoxin (toxoid) subcutaneously together with "the dose of serum indicated by the circumstances." On the 20th day and again on the 30th day, 2 cc of toxoid was given subcutaneously. Antitoxin titrations done six months later showed that 97 per cent of the subjects had 0.065 to 0.2 (international) unit of tetanus antitoxin. After one year an additional dose of 2 cc of toxoid was given and six months later, when 51 were retested, 96 per cent had more than $\frac{1}{10}$ unit and 76 per cent 1 unit or more.

10,000 units of tetanus antitoxin intramuscularly
 1.0 cc of tetanus toxoid (alum precipitated) subcutaneously
 1.500 units of tetanus antitoxin intramuscularly

When larger (therapeutic) doses of antitoxin are given together with toxoid, the development of demonstrable active immunity may require a prolonged period of repeated antigen injections and the lapse of several months. The observations by Ramon,⁹ who has advocated this procedure of simultaneous immunization are the only ones reported in sufficient detail to be of value for analysis. This report comprises 14 patients each of whom received 150,000 (international) units of tetanus antitoxin together with 2 cc of anatoxin (toxoid). At weekly intervals increasing doses of toxoid were given (3 cc in one week, 4 cc in two weeks, 5 cc in three weeks, 5 cc in four to seven weeks and sometimes 5 cc later) and titrations of tetanus antitoxin followed. The early high antitoxin titers

fell rapidly to lower levels and the later decrease in titer was more gradual. In every instance there was eventually an increase in antitoxin as evidence of the production of an active immunity which appeared two weeks after a toxoid injection. Most cases, however, required a total of six injections of toxoid (24 to 29 cc), and the development of active immunity was not demonstrated for four months or more (seventeen weeks 2, nineteen weeks 3, twenty-three weeks or more 4), although 3 patients showed some increase in antitoxin at the end of eight weeks and 2 others at ten weeks. It was of interest also that in most instances the (passive) antitoxin had fallen to a relatively low level before a stimulating dose of toxoid caused a rise in titer. For example, in 5 cases the titer had reached less than 0.01 unit, while in 7 others it had fallen to 0.1 unit or less. It was assumed by Ramon that the early 'simultaneous' dose of toxoid was necessary or at least played a very important part in the sensitization. It may be pointed out, however, that the evidence previously mentioned of the inhibiting effect of antitoxin on sensitization by early doses of toxoid, the multiple doses of toxoid given at intervals during the period of decreasing passive immunity and the considerable delay in the development of active immunity all suggest that one of the later doses of toxoid may have initiated the sensitization and that the initial "simultaneous" toxoid may have been entirely without effect. Experiments were carried out to study this possibility.

EXPERIMENTAL OBSERVATIONS ON "SIMULTANEOUS" SERO-VACCINATION AND DELAYED IMMUNIZATION AFTER ANTITOXIN

These were planned on the hypothesis that since the presence of an excess of passive antitoxin inhibits the production of active immunity with toxoid, the stimulation of active antibodies will occur only when the passive immunity has reached a low level. If this is correct, there is an optimum time after passive immunization at which the inhibition disappears and the stimulation of an active immunity becomes effective, while toxoid given before this time is rendered inert by the heterologous antitoxin. Several properly spaced injections of toxoid delayed until the approximate time of low passive immunity would therefore be as effective as when the toxoid was started simultaneously with the antitoxin injection. For this it seems preferable to use alum toxoid which is insoluble and presumably is dissolved and absorbed slowly and continuously over a period of time so that antigen will become available for the stimulation of an active immunity as soon as the inhibition by antitoxin disappears. It is apparent that when smaller amounts of antitoxin have been given a shorter delay in starting toxoid is indicated than after large doses.

The effect of "simultaneous sero-vaccination" was compared with that resulting from a delay in the start of toxoid immunization for two, four and six weeks after the antitoxin injections in the following manner.

Twelve healthy children (from the Shriner's Hospital) were each given 10,000 units of tetanus antitoxin intramuscularly and separated into four groups of 3.

GROUP 1—Each child was given 0.5 cc of alum precipitated tetanus toxoid subcutaneously at the time of the antitoxin injection and every two weeks thereafter for a total of six injections.

GROUP 2—Toxoid was started two weeks after the antitoxin and continued every two weeks for a total of five injections.

15. Sacquepée E. and Jude A. Sur la valeur et la durée de l'immunité antitétanique après injection de rappel chez l'homme immunisé contre la tétanos par l'emploi simultané du sérum et de l'anatoxine tétanique. *Compt. rend. Soc. de biol.* 125: 711 (June 26) 1937.

GROUP 3—Toxoid was started four weeks after the antitoxin and given again every two weeks for a total of four injections

GROUP 4—Toxoid injections were delayed until six weeks after the antitoxin, and a total of three doses was given

An additional group of 3 children (group 5) was given only 1,500 units of antitoxin and toxoid was started two weeks later and continued at two week intervals for a total of five doses

The observations covered a period of twelve weeks and antitoxin titrations were done on the blood of each child at the start of the experiment and at two week intervals thereafter

The observations in these five groups have been collected in table 4, in which the biweekly antitoxin titrations are shown. The early high levels of antitoxin fell gradually, and the variation observed in the rate of disappearance of antitoxin in different children could not be related to a previous dose of horse serum since only 1 child (group 5, case 2) had had such an injection (diphtheria antitoxin). The complete destruction of 10,000 units of antitoxin within two weeks of its injection in 1 child (group 3, case 1) was quite unexplained, since she had received no previous horse serum. This child had severe serum sickness seven days after the antitoxin injection, but this occurred also in 7 other children in the series. The earliest increase in antitoxin titer is indicated in heavier type and is taken as the first development of an active immunity.

The results in this series also appear quite clearcut and definite. It will be noted that in the first four groups of children passively immunized with 10,000 units of antitoxin, all began to have an active immunity from the 8th to the 12th week of observation. While there was some inconstancy in the onset of active immunity in the different groups, this variation was no greater than that shown by the children in the same group. In these children, then, an active immunity developed at approximately the same time, whether the toxoid was started simultaneously with the antitoxin injection or two, four or six weeks later. On the other hand one of the relatively constant and striking features was the low titer of passive antitoxin reached before the appearance of an active immunity. This was 0 in 7 children, 0.017 unit in 3, 0.01 unit in 1 and 0.05 unit in 1, which suggests that the disappearance of the inhibiting effect of passive antitoxin is more important in the early development of active immunity than the time at which the immunization is started. This is emphasized by the 3 children in group 5, each of whom was passively immunized with only 1,500 units of antitoxin. In them the passive immunity disappeared more quickly than in those given larger doses and fell to 0 in from four to six weeks. Although toxoid was not started until two weeks after the antitoxin, active immunity had begun to develop in all six weeks later.

Further observations of a comparison between "simultaneous serovaccination" and delayed immunization were possible on 2 children with clinical tetanus each of whom was given 100,000 units of antitoxin (cases 6 and 8). The detailed data of these 2 children are given in the protocols at the end of the paper, but a graphic representation of the results is shown in the accompanying chart. In case 6 active toxoid immunization was started simultaneously with the antitoxin injection and continued once weekly for five injections and thereafter once every two weeks. In case 8 toxoid was first given three weeks after the antitoxin and

again every two weeks afterward. Antitoxin titrations were done at weekly intervals during a period of thirteen weeks and are expressed in units.

The antitoxin curves in these 2 cases show a striking similarity. From an early level of 20 to 40 units the titers fell to 1 unit at the end of four weeks and to 0.1 unit at seven weeks. In the first child (case 6) in whom toxoid immunization was started simultaneously with the antitoxin, the first demonstrable increase in antitoxin (active immunity) appeared nine weeks later following the seventh toxoid injection while in the second child (case 8) in whom the toxoid immunization was delayed for three weeks an active immunity developed in the 10th week of observation following the fourth toxoid injection. In both instances the appearance of an active immunity was delayed until the passive immunity had reached a low level and the early toxoid injections in the first case produced no appreciable acceleration in its development.

These results tend to confirm the relative inefficacy of toxoid given during moderate and high concentrations

Transition from passive to active tetanus immunity (indicated by X) after 100,000 units of antitoxin. Comparison of simultaneous serovaccination (case 6) with delayed toxoid immunization (case 8) by blood antitoxin titer.

of passive antitoxin and suggest that only when such passive immunity has reached a relatively low titer is active immunization with toxoid effective. They give no support to the value of "simultaneous" serovaccination and indicate that a transition from passive to active immunity is readily accomplished by delaying the start of active toxoid immunization from two to four weeks after the passive immunization depending on the dose of antitoxin given.

SUMMARY

In a study of active and passive tetanus immunity on 39 children on whom more than four hundred tetanus antitoxin titrations were done, the following observations were made:

1. Although passive immunization with the usual prophylactic dose of 1,500 units or less produces an immunity of only approximately three weeks, larger doses cause a much more prolonged immunity. After the administration of 100,000 units or more it was found that the blood serum showed as much as 1 unit per

cubic centimeter for from three to four weeks, 0.1 unit from six to ten weeks and 0.01 unit from eight to eleven weeks. With a dose of 10,000 units the passive immunity was somewhat less prolonged, although in most instances 0.1 unit persisted for from four to six weeks and 0.01 unit from six to ten weeks.

2. Antitoxin in the spinal fluid of 2 children was determined during passive immunization. In 1 the spinal fluid contained 0.2 unit per cubic centimeter when the blood antitoxin titer was 30 to 50 units, while in the second the spinal fluid titer was 0.017 unit and the blood 70 units.

3. In 4 children with clinical tetanus it was observed that not only did antitoxic immunity not follow recovery but the amount of antigen (toxin) absorbed during a tetanus infection was so small as to produce no primary antigenic stimulus or "sensitization" to later active tetanus immunization.

4. Repeated subcutaneous or intracutaneous injections of tetanus toxoid did not produce an antitoxic immunity within several weeks. Such injections are of value in tetanus prophylaxis only when the subject has had one or more previous "sensitizing" toxoid inoculations.

5. When passive immunization was produced with 10,000 units or more of antitoxin, multiple injections of toxoid given subcutaneously or intracutaneously during the week following had no demonstrable immunologic effect. Such subjects did not have any active immunity for a period of many weeks and even when given a later "stimulating" dose of toxoid failed to respond by producing antitoxin. Control groups of children given toxoid in the same manner without being passively immunized reacted to the later dose by developing an active immunity in a short time. It was concluded that the presence of any considerable quantity of heterologous antitoxin prevents the usual "sensitization" of the body cells by toxoid and renders it inert as an antigen.

6. A passive immunity can be converted into an active immunity by toxoid injections. It was observed, however, that this transition can be produced as readily and as rapidly when the initial active toxoid injection is delayed several weeks as when it is started simultaneously with the antitoxin injection. After passive immunization with 10,000 units of antitoxin and with toxoid injections at two week intervals an active immunity developed in from eight to twelve weeks regardless of whether the first toxoid was given simultaneously with the antitoxin or whether it was delayed two, four or six weeks. The same similarity of active antitoxin response was found in 2 children passively immunized with 100,000 units. In 1 of them toxoid was started simultaneously with the antitoxin injection while in the other the initial injection was delayed three weeks but in the two the active immunity developed at about the same time.

It was concluded that these results were explained by the previously mentioned observations of the inhibition of larger amounts of heterologous antitoxin on the antigenic action of toxoid and that only when such passive antitoxin titers have reached a relatively low level is active toxoid immunization effective. This hypothesis was supported by the observation that a much more rapid active immunity could be produced after passive immunization with only 1,500 units of

antitoxin. Under such circumstances the passive antitoxin titer falls more quickly, and children in whom toxoid was started two weeks after the antitoxin injection had an active immunity more quickly than those who had received larger doses (10,000 units) of antitoxin. These observations tend to refute the value of "simultaneous serovaccination" in the production of active tetanus immunity and show that a delay of active immunization of from two to four weeks following the antitoxin injection is indicated.

BRITISH PROTOCOLS OF CASES OF CLINICAL TETANUS IN WHICH IMMUNITY STUDIES WERE MADE

All 9 children in this group recovered except 1. They were given avertin with amylene hydrate for varying periods, but the details of therapy are omitted. All lived in rural or suburban localities at some distance from St. Louis and in some of them prolonged observation was not possible. The immunologic data are collected in table 1 and those on cases 6 and 8 shown graphically in the chart.

CASE 1—Ruby C. aged 5 years with tetanus of four days duration was given 200,000 units of antitoxin intramuscularly over a period of four days. Twelve days after the last serum was given the blood showed 20 units and five days later 10 units. No further tests were done.

CASE 2—Norman B. a girl aged 8 years with tetanus of three days duration was given 90,000 units of antitoxin intravenously and 10,000 units subcutaneously on the first day of observation and 50,000 units intravenously two days later. Alum precipitated tetanus toxoid was given subcutaneously each day for the first seven days in 0.5 cc doses. On the 3d day the blood showed 50 units of antitoxin and the spinal fluid 0.2 unit; on the 9th day the titer was 30 units in the blood and still 0.2 unit in the spinal fluid. Examination of the blood showed 20 units on the 13th day, 10 on the 15th, 0.5 on the 30th day and 0.1 on the 68th. On the 74th day, 1 cc of alum precipitated toxoid was given subcutaneously and six days later (80th day) the antitoxin titer was 0.017 unit while on the 125th day it had fallen to 0.003. At this time another dose of 0.5 cc of alum precipitated toxoid was given subcutaneously. Two months later (177th day) 0.5 unit was found in the blood and a final dose of 0.5 cc of alum precipitated toxoid was injected subcutaneously with the development of an antitoxin titer of 5 units two weeks afterward (185th day).

CASE 3—Ruth R. aged 10 years with clinical tetanus of eight hours duration was given 20,000 units of antitoxin intravenously and 30,000 units intramuscularly on the first day of observation and 50,000 units intramuscularly the day following. Daily doses (0.5 cc) of toxoid alum precipitated were given intracutaneously for the first seven days. The serum titers of antitoxin showed the following: 3d and 4th days 20 units; 5th to 10th day 10 units; 12th day 7.5 units; 15th day 5 units; 20th and 24th day 2.5 units; 27th and 32d day 1.0 unit; 37th day 0.5 unit; 47th day 0.2 unit; 57th day 0.1 unit; 76th day 0.017 unit and 111th day less than 0.003 unit. On this day 1 cc of alum precipitated tetanus toxoid was given subcutaneously, and seven days later (118th day) the blood still showed no antitoxin although thirty days after this injection (141st day) the serum titer was 0.2 unit. No further observations were made for five and one half months, at which time the blood showed 0.05 unit. A final dose of 1 cc of alum toxoid was given subcutaneously and the antitoxin increased to 2 units after one week and to 5 units after two weeks.

CASE 4—Clement H., a boy aged 13 years with clinical tetanus was given 100,000 units of antitoxin on the first day of observation. The serum antitoxin titers were as follows: 4th day 20 units, 9th day 10 units, 14th day 5 units, 29th day 0.5 unit, 43d day 0.1 unit, 57th day 0.01 unit, 85th day less than 0.003 unit. One month later the blood still

showed no antitoxin, and 1 cc of plain tetanus toxoid was given subcutaneously. After two months the titer was still less than 0.003 unit.

CASE 5—Charles K, a boy aged 13 years, with clinical tetanus, received 50,000 units of antitoxin intravenously the first day of observation and 50,000 units by the same route the day following. On the 3d day the serum showed 30 units, on the 17th day 2 units and on the 24th day 1 unit. No further observations were possible.

CASE 6—Geneva G, a Negro girl aged 3 years, was burned severely over the abdomen and legs. Clinical tetanus developed eighteen days later for which she was given 40,000 units of tetanus antitoxin intravenously and 60,000 units intramuscularly together with 1 cc of alum precipitated tetanus toxoid subcutaneously. She received weekly subcutaneous injections of alum precipitated toxoid during the next four weeks (five injections), and these were continued at biweekly intervals subsequently. Antitoxin titrations of the blood done weekly are shown in table 5.

CASE 7—Raymond N, a boy aged 7 years, with very severe tetanus was given 50,000 units of antitoxin intravenously and the same amount intramuscularly. The following day his blood showed 70 units per cubic centimeter and the spinal fluid 0.017 unit. Death occurred on the second day, apparently from peripheral circulatory collapse.

CASE 8—Mary W, aged 6 years, with clinical tetanus, received 100,000 units of antitoxin half intramuscularly and half intravenously. Active immunization with toxoid was started three weeks later. The antitoxin titrations are shown in table 6.

CASE 9—Clyde C, a boy aged 6½ years, had mild clinical tetanus of two weeks' duration when first seen and was given no antitoxin. His blood showed no antitoxin when examined on the 4th, 13th, 20th and 37th days of observation. On the 37th day he was given 1 cc of tetanus toxoid subcutaneously and no antitoxin developed by the 44th, 51st or 100th day.

THE SYNDROME OF UNILATERAL RUPTURE OF THE SIXTH CERVICAL INTERVERTEBRAL DISK

WITH COMPRESSION OF THE SEVENTH CERVICAL NERVE ROOT

A REPORT OF FOUR CASES WITH SYMPTOMS SIMULATING CORONARY DISEASE

R. EUSTACE SEMMES, M.D.

MEMPHIS, TENN.

AND

MAJOR FRANCIS MURPHEY

MEDICAL CORPS ARMY OF THE UNITED STATES

Rupture of a cervical intervertebral disk into the spinal canal has been reported many times. With few exceptions, however, the symptoms were due to compression of the spinal cord rather than the nerve roots. Adson,¹ Elsberg,² Stookey,³ Peet and Echols,⁴ Mixer and Ayer,⁵ Hawk,⁶ Love and his co-workers⁷ and Bradford and Spurling⁸ all have reported 1 or more cases of rupture of the cervical disks. Of all these cases only 4 seem to have had nerve root compression without involvement of the spinal cord, and of these 1⁹ was a rupture of the sixth disk. In this particular case the description of the exact radiation of the pain and of the sensory findings was quite limited. Two of the cases¹⁰ were not proved pathologically, but there seems to be very little doubt of the diagnosis.

From a review of the literature, therefore, it would seem that most of the ruptured disks in the cervical spine produce either bilateral or unilateral cord pressure and that disks causing nerve root symptoms alone are very rare. Indeed, such statements have been made by several of the authors who have written on this subject, namely Stookey,¹¹ Love and Walsh¹² and Bradford

and Spurling.⁸ We believe, however, that exactly the reverse is true. We believe further that an undetermined number of patients with pain in the precordium, in the shoulder and in the arm, who heretofore were thought to have coronary thrombosis, angina pectoris, arthritis of the cervical spine, brachial plexus neuritis and neuralgia, bursitis, scalenus anticus syndrome, cervical rib or discogenetic disease will be found to have a rupture of one of the lower cervical disks.

Unilateral rupture of the sixth cervical disk with compression of the seventh cervical nerve root causes a definite syndrome as similar lesions of the fourth and fifth lumbar disks. This report is based on 3 such cases proved at operation. One other case as yet unverified by operation is included, because the similarity of the history and physical findings to the 3 proved cases makes the diagnosis almost certain. All 4 cases are practically identical.

ANALYSIS OF CASES

Three of the patients were men and 1 was a woman. Two of the patients were physicians. The youngest was 40 years of age and the oldest 51. In all cases the pain was on the left side. The duration of symptoms varied from seven years to three weeks.

Each patient gave a history of numerous cricks in the neck recurring intermittently for months or years preceding the attack of radiating pain. The onset was precipitated in 1 case when the neck was jerked suddenly while the patient was driving a car and in another when the patient bent over to tie his shoe. In the 2 remaining cases there was no definite movement or injury to which the onset could be attributed. Each patient had a particularly severe crick in the neck before the rather sudden onset of the disabling pain. The pain radiated in each case to three general regions: (1) the precordium, (2) a point just medial to the upper angle of the scapula and (3) down the lateral and medial surfaces of the arm. In each instance there was considerable difficulty in breathing and a sense of impending death and in 1 case cyanosis. At the beginning of the attack, the pain in the precordium was most intense and every patient thought that he had had a heart attack. After a few days or weeks this pain abated to some extent and that in the rhomboid region and arm became more pronounced. All pain was intensified by moving the neck, sneezing, coughing and straining. Three patients complained of definite numbness and weakness in the index finger and slight numbness in the middle finger. The same 3 patients also stated that the involved arm was always cold.

Examination showed severe muscle spasm in the neck and shoulder. The neck was held rigidly and abduction of the neck from the side of the lesion caused an exacerbation of the pain, while traction on the head relieved the symptoms to some extent. In each patient there was an exquisitely tender point just posterior to the scalenus anticus muscle over the exit of the seventh cervical nerve from the spinal canal. There was also a point of tenderness over the painful area in the rhomboid region. In 3 cases pronounced hypesthesia and hypalgesia were found over the entire index finger which extended to the metacarpophalangeal joint. In these same 3 cases there was slight reduction of sensation in the middle finger. In 1 case no objective sensory disturbance was found. In 3 cases there was weakness in the movement of the index finger, particularly in flexion. The reflexes were normal in all cases and there was no evidence of muscular atrophy. There were no

findings in any case suggestive of spinal cord pressure, although 1 patient had a conditional tremor in the opposite hand, which is still unexplained.

X-ray examination of the cervical spine showed a straightening of the cervical curve in each instance. There was no evidence of hypertrophic arthritis in any of these cases at the beginning of symptoms. In 1 case, however, reexamination of the neck seven years after the onset and shortly before operation showed narrowing of the fifth and sixth disks with tipping of the edges of the adjacent vertebrae. Another patient is beginning to show spur formation on the sixth and seventh vertebrae one year after the operation.

Lumbar puncture was performed on all 4 patients. The total protein was increased in 2 and was normal in 2. The dynamics of the fluid were normal in all 4 cases.

The diagnosis of this condition was made solely on the basis of the history and physical findings. No contrast medium in the spinal canal was used by us although in 1 case iodized poppy seed oil had been injected elsewhere with negative results. In this case and in 1 other the ruptured disk was so far out in the intervertebral foramen that the nerve alone was compressed. Contrast mediums could not have shown these lesions but in a third case there was some slight indentation of the dura which might have produced a filling defect.

The operative procedure was carried out under local anesthesia. The lower cervical laminae on the side of the lesion were exposed and the involved nerve root was identified by the patient when gentle pressure was applied on the ligamentum flavum reproducing the exact pain. In each instance the ruptured disk was found directly beneath. This test was made before any bone was removed eliminating the necessity of exploring several interspaces. A small portion of the adjacent laminae was removed and the interlaminar portion of the ligamentum flavum was excised. As this was done, the nerve root came into view, pushed up against the ligamentum flavum and was flattened out by the nodule of disk.¹³ The nerve root then was injected with procaine hydrochloride and almost instantaneously all pain was relieved. Approximately half of the articular facets and the capsular portion of the ligamentum flavum were removed and the nerve root was retracted upward or downward exposing the nodule of disk without difficulty. These herniated disks differed from those found in the lumbar region only in size being smaller than the latter. The loose fragments of fibrocartilage were removed, thus relieving the pressure on the nerve.

Two of the 3 patients operated on now are relieved completely of all of their original pain, whereas the third although relieved of the shoulder pain still has some discomfort in the arm and occasional pain in the precordium. He states, however, that this is not nearly as intense as before the operation and feels that the operation was well worth while. The patient who was not operated on was seen by us before the cause of her pain was recognized. She gradually has improved to the point at which she is able to continue her work but still has occasional pain at intervals, especially after periods of activity.

13 It should be remembered that in the cervical region the nerve roots emerge from the dura at the level of the foramina through which they make their exits and are compressed as they go through the foramina whereas in the lumbar region the nerve roots come out of the dura and are compressed by the ruptured disks a segment above the points of their exit from the canal.

REPORT OF CASES

CASE 1—History of cricks in neck for three years prior to onset of severe pain in neck, rhomboid region, arm and precordium, which lasted seven years, injection of iodized oil with negative results, scalenus anticus section without relief, removal of rupture of sixth cervical disk with partial relief of symptoms

History—J W B, a white man aged 41, a surgeon admitted to the Willis Campbell Clinic on Aug 2, 1933, complained chiefly of violent pain in the left side of the neck the precordium, the rhomboid region and the left arm. During the last three years the patient had had three very severe cricks in the left side of the neck.

Three weeks before admission the patient had a severe crick in the neck and a few days later experienced intense pain associated with muscle spasm in the left rhomboid region. A short time thereafter an extremely violent radiating pain occurred in the precordium and down the left arm. This pain completely incapacitated him and he spent most of the time in bed, taking large doses of codeine and soluble pentobarbital. One week before admission he consulted an internist because he thought he had a coronary occlusion with an atypical distribution of pain. Complete investigation of the heart, however, failed to reveal any evidence of coronary disease.

Examination—The neck was held rigidly and there was considerable muscle spasm in the left rhomboid region. There was definite tenderness over the brachial plexus and over the painful area in the rhomboid region. There was no weakness in the hand nor was there any change in sensation in the arm or fingers. All reflexes were normal.

X-ray examination of the cervical spine showed that it was held in slight flexion but was otherwise negative.

Diagnosis—Brachial plexus neuralgia, cervical arthritis and like conditions were considered.

Course—Injection of procaine hydrochloride into the brachial plexus, head traction and a Thomas collar were tried, with only temporary relief. The pain continued in such intensity that it was impossible for him to continue his practice. Many internists, neurologists and neurosurgeons in various parts of the country were consulted in the next six or eight months. At one clinic an exploration of the rhomboid region was made, which was entirely negative. During the next three years he spent his winters in Arizona and summers in Wisconsin, where he thought the pain was less severe than at his home in Arkansas. A conditional tremor of the right arm and hand developed during this period. During the winter of 1937 the pain again became almost unbearable and he was referred to yet another neurosurgical clinic for investigation.

Neurologic examination was again entirely negative, but examination of the spinal fluid showed a consistently high total protein of 60 mg per hundred cubic centimeters, and it was felt that there was some pressure on the fifth or sixth cervical nerve root. Intraspinal injection of iodized poppy seed oil was carried out with negative results. The tremor in the right arm was thought to be functional. In 1938 the patient returned to Memphis and a section of his scalenus anticus muscle on the left was carried out without relief of symptoms.

In September 1940 the patient experienced an exacerbation of the pain so intense that he was certain this time that he did have a coronary occlusion. Again investigation of his heart failed to reveal any abnormality. There was no change in the neurologic findings, and the spinal fluid protein was again found to be 60 mg.

X-ray examination at this time showed a very definite narrowing of the fifth and sixth cervical disks with considerable spur formation along the edges of the fifth, sixth and seventh cervical vertebrae.

It so happened that the patient's return to Memphis for investigation coincided with the admission of L G (case 2) to the John Gaston Hospital. Comparison of the symptoms and physical manifestations in these 2 cases showed that they were identical, with the exception of the lack of sensory change in the first case. Five days after the removal of the sixth cervical disk in case 2, J W B's sixth cervical disk was explored and a very definite rupture of the disk was found and removed. When the seventh cervical nerve root was injected with procaine hydrochloride, the relief of pain was instantaneous, the

index finger became almost anesthetic and the middle finger hypesthetic. Some pain in the arm recurred immediately following the operation. The pain in the neck and in the rhomboid region was relieved entirely and only occasionally did he have any pain in the precordium.

One year after the operation the patient writes that he has felt fairly well during the summer. He still has moderate pain in the arm and occasional pain in the precordium, which is brought on by exertion. He feels that, although he is not relieved entirely, the operation has been well worth while. The conditional tremor in the right arm continues and is still unexplained.

CASE 2—History of cricks in neck intermittently for three or four years followed by violent pain in the left shoulder, precordium and left arm for two weeks, removal of rupture of sixth cervical disk with complete relief

History—L G, a white man aged 45, a carpenter, admitted to the John Gaston Hospital Sept 17, 1940, complained chiefly of a crushing pain in the neck, precordium, shoulder and arm.

For the last three or four years the patient had had frequent cricks in the neck which lasted only a few days and had not been incapacitating. In addition, he had had occasional sharp pains in the precordium and left arm which lasted only a few minutes at a time.

Two weeks before admission the patient bent over to tie his shoe and was seized suddenly with a violent pain in the left side of the neck, which radiated into the heart, the left shoulder and the left arm. The pain was so intense that at times it was difficult for him to breathe. He called a physician, who gave him a large dose of morphine with some relief. The following day, however, the pain was as intense as ever and he noticed that the index finger on the left hand was quite numb and that the middle finger was slightly numb. Since the onset the pain had been agonizing and completely disabling. He had been able to sleep very little except when under the influence of opiates. He noticed that any movement of the neck accentuated the pain and that supporting the left arm with the right gave him some relief. Coughing, sneezing or straining aggravated the symptoms. Since the onset of pain the patient had noticed that his left hand and arm felt cold all the time.

Examination—The patient was in obvious pain. The neck was held rigidly toward the left and slightly forward. The left arm was supported by the right. Passive movement of the neck or traction on the involved arm intensified the pain. There was considerable muscle spasm in the neck and in the left shoulder, and there was a point of definite tenderness over the brachial plexus just posterior to the scalenus anticus muscle. The entire left index finger was almost completely anesthetic, and there was moderate hypesthesia of the left middle finger. There was slight weakness of the index finger on flexion but no other weakness in the arm. The reflexes were normal and no temperature change in the arm was noticed. Blood pressure was the same (125 systolic and 85 diastolic) in both arms and the radial pulse was felt easily.

X-ray examination of the cervical spine showed a loss of the normal cervical curve but was otherwise negative.

Spinal fluid examination showed normal dynamics and a total protein of 50 mg per hundred cubic centimeters.

The diagnosis was rupture of the fifth or sixth cervical intervertebral disk.

Course—An exploration of the spinal canal was advised. To this the patient readily agreed, stating that he could not bear the pain much longer.

On September 24 a subtotal hemilaminectomy was performed. When the ligamentum flavum between the sixth and seventh cervical laminae on the left was pressed on, the old pain was reproduced in all its intensity. A small part of the adjacent lamina was removed and when the ligamentum flavum was dissected out the seventh cervical nerve root was exposed. It was pushed backward and flattened out by rupture of the sixth disk. The loose fragments of fibrocartilage were removed without difficulty, and the nerve root was completely decompressed.

Following the operation the patient was entirely relieved of all of his pain and has remained so to the present time. The muscle spasm in the neck and shoulder subsided as the sore-

ness from the operative wound diminished and the sensory disturbance in the index and middle fingers began to clear up.

One year after the operation the patient states that he never has any more pain in the left arm, shoulder or precordium but recently has begun to have a little pain in the right side. The left index finger is still slightly hypesthetic over the distal phalanges, the middle finger is entirely normal. X-ray examination of the cervical spine now shows beginning spur formation along the edges of the sixth and seventh cervical vertebrae.

CASE 3—Three year history of cricks in the neck culminating in a violent attack of pain simulating coronary occlusion removal of rupture of sixth cervical disk with complete relief of pain

History—R. B. McC., a white man aged 47, a pediatrician, admitted to the Baptist Memorial Hospital Aug. 16, 1941, complained chiefly of violent pain in the neck, precordium, left shoulder and left arm.

For the past seven years the patient had had attacks of mild precordial pain with no radiation whatever. Electrocardiograms had been made during this period which failed to reveal any changes suggestive of coronary disease. For the past three years the patient had had twenty or thirty cricks in the left side of the neck. Neither of these disturbances, however, incapacitated him, and he was able to carry on a very active practice.

Three weeks before admission, while driving his car, the patient received a severe jar to his neck. A few hours later what he thought was a typical crick in the left side of the neck developed. Three days later, while playing pool he missed the cue ball entirely, again jerking his neck forward, and instantly experienced such an agonizing pain in the neck that it almost knocked him down. The pain radiated to a point just medial to the upper angle of the left scapula and continued throughout his illness.

On the day before admission he noticed a burning sensation in his left arm from the elbow to the finger tips. A few hours later his left index finger became almost entirely anesthetic and the left middle finger became slightly numb. During the night before admission he was awakened by a violent pain in the left shoulder, precordium and left arm. After he had taken a sedative, the pain abated to a certain extent. Shortly after he arrived at his office the next morning, the pain again became so violent that he was able to breathe only with the greatest difficulty. Several physicians were summoned hurriedly and they found the patient in excruciating pain, quite cyanotic and breathing with considerable difficulty. The blood pressure was 132 systolic and 80 diastolic. The heart was regular with a rate of 70.

He was given a quarter of a grain (0.016 Gm.) of morphine sulfate and as soon as the pain subsided to some extent he was moved to the Baptist Memorial Hospital. When he lay down in bed the pain almost disappeared, but when he sat up it would recur. An electrocardiogram was made on admission and revealed the following abnormalities: In lead I the T wave was barely above the isoelectric line. In lead 4 the R wave was 3 mm. in height, otherwise the tracings were normal. It was felt that he had coronary occlusion and during the next three days he was kept in an oxygen tent most of the time. The pulse ranged from 66 to 90. There was no fever, no shock, no pericardial friction rub, no leukocytosis or any other constitutional evidence of infarction. On the second hospital day another electrocardiogram showed that the T waves in leads 1, 2 and 3 had become flattened and that the R wave in lead 4 was 3 mm. in height as before. On the third day after admission it became increasingly evident that the pain was not that of coronary occlusion but was explainable on the basis of involvement of the cervical nerves. Five days after admission we were called in to see the patient.

Examination—The neck was held rigidly and slightly to the right. There was definite muscle spasm in the left side of the neck and in the left shoulder. Any movement of the neck precipitated a severe attack of pain and traction downward on the left shoulder did likewise. Traction on the head gave considerable relief. There was a point of exquisite tenderness over the brachial plexus just posterior to the scalenus anticus muscle and one of moderate tenderness over

the scalenus anticus muscle itself on the left. There was also a tender area just medial to the upper angle of the scapula over the left rhomboid muscles. There was some weakness of the left index finger, particularly on flexion. Sensory examination showed almost complete anesthesia of the entire left index finger and slight reduction of sensation in the left middle finger. The reflexes were normal and the blood pressure in the two arms was the same.

X-ray examination showed loss of the cervical curve but otherwise was negative.

Spinal fluid examination showed normal dynamics, normal cell count and a total protein of 25 mg. per hundred cubic centimeters.

The diagnosis was rupture of the sixth cervical disk with compression of the seventh cervical nerve root.

Course—Head traction was applied. This was followed by considerable relief of pain for several days. Injection of procaine hydrochloride into the painful area just medial to the upper angle of the scapula gave immediate and complete relief of all pain for several hours. Electrocardiograms on the seventh month and seventeenth days after admission revealed a gradual return of normal pattern. Head traction was continued for about three weeks, however, during the latter part of this time the pain again became more intense and it was decided that removal of the disk should be undertaken.

On September 12 under local anesthesia the laminae of the sixth and seventh cervical vertebrae on the left were exposed. Pressure on the ligamentum flavum between the sixth and seventh cervical laminae immediately reproduced all of the old pain. Approximately half of the sixth and seventh cervical laminae was removed and the ligamentum flavum dissected out revealing the seventh cervical nerve root pushed backward against the edge of the articular facets and the remaining ligamentum flavum by a small mass approximately a quarter of an inch in diameter. The nerve root was injected with procaine hydrochloride and about half of the articular facets removed. The nerve root then was retracted upward revealing a typical ruptured disk. The capsule of the disk was incised and three small fragments of loose fibrocartilage were lifted out. Following this, the nerve root was quite free in all directions and no attempt was made to remove the remainder of the nucleus between the vertebrae.

Since the operation the patient has been entirely free of pain. The sensory disturbance of the index finger is improving while that of the middle finger has disappeared. Six weeks after the operation he resumed his practice and has continued it without difficulty.

CASE 4—Agonizing pain in neck, left shoulder, precordium and left arm for three months procaine injection of thoracic sympathetic ganglia and brachial plexus diathermy and other therapy without relief, gradual recovery over a period of three years

History—Mrs. F. S., a white woman aged 51 an organist, admitted to the Girty-Ramsay Hospital May 26, 1938, complained chiefly of agonizing pain in the left side of the neck, left shoulder, left arm and precordium for three weeks. She had had occasional cricks in the neck for years.

Three weeks before admission to the hospital the patient had a severe pain in the left side of her neck which radiated to the base of the skull. Two days later, while driving her car, she experienced a sudden violent pain which shot from the neck into the precordium to the shoulder and down the medial and lateral aspects of the left arm to the finger tips. Pain was so intense that she could hardly breathe and she was quite certain that she had a heart attack and surely would die. She was taken home and put to bed where much to her surprise the pain was relieved to a considerable extent but would recur as soon as she assumed the upright position. Her physician who was called felt that she did not have a heart attack but rather some type of neuritis of the brachial plexus. Large doses of opiates were given, with partial relief. The following morning the patient noticed that there was no feeling in the entire left index finger and that she could move it only with the greatest difficulty. There was also some numbness in the left middle finger. The pain soon became constant, whether the patient was in the upright or the prone position.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Present Status of Serum Lipase Test—Further confirmation of the specificity of the serum lipase test is presented by Johnson and Bockus, who from some twelve hundred determinations utilize for their discussion 21 cases of acute pancreatitis, 1 of chronic pancreatitis and 30 of pancreatic cancer. The serum lipase value was above 1 cc at least once during the course of the illness in 17 (81 per cent) of the 21 cases of acute pancreatitis and in 16 (53.3 per cent) of the 30 with cancer of the pancreas. Analysis suggests that the decrease in serum lipase concentration, following an initial elevated serum lipase, may be due to the subsiding of an inflammatory process or to complete destruction of the pancreas. The serum lipase curve in the 1 case of chronic pancreatitis was indistinguishable from that in cancer of the pancreas. The serum lipase curves in pancreatic cancer suggest that its initial elevation is due to an obstruction to the free flow of pancreatic juice. The subsequent decrease is due either to replacement of pancreatic tissue by the malignant process or to impaired pancreatic function secondary to prolonged pancreatic duct obstruction.

Gastric Mucosa, "Gastritis" and Ulcer—Wolf and Wolf describe the changes to various stimuli of the gastric mucosa of a 57 year old subject with a permanent gastric fistula 3.5 cm in diameter, surgically produced in 1895 because of benign stricture of the esophagus. The congested mucosa was especially susceptible to injury; this suggests that vascular engorgement might predispose to the development and persistence of erosions and changes secondary to inflammation. Sustained hyperemia of the gastric mucosa was accompanied by symptoms of abdominal discomfort and pain. However, after a fast of twelve or more hours that is, resting gastric mucosa, if the mucosa was struck a sharp blow with the side of a glass rod the area struck became blanched and depressed within one second. It remained so for one to five seconds depending on the force of the blow. Following this, a slight transitory hyperemia occurred in the same region, which lasted for three to ten seconds. Strong irritants and corrosive agents failed to cause more than a slight

to moderate erythema in the gastric mucosa, while they caused a decided reaction with destruction of tissue when applied in similar concentration to the skin. This indicates that the cells lining the stomach are endowed with some special protection against chemical injury. Presumably the special protection is afforded by the thick layer of tenacious mucus adherent to the lining of the stomach and is elaborated in increasing amounts in response to physical and chemical stimuli. To test this protective power, a part of the gastric mucosa was deprived of this covering and then the area was subjected to 10 normal hydrochloric acid. Within two minutes a thick layer of grayish opaque mucus appeared over the area exposed to the acid. The application of the drops of acid was increased from twelve to twenty a minute, while the accumulated mucus was sucked away through a pipet. Within five minutes the mucosa beneath became moderately reddened and edematous. Then a mustard suspension was applied, and within five minutes the redness and edema was further accentuated and minute bleeding points became evident as pinpoint black specks on the mucosa. A sharp blow with a glass rod to the gastric mucosa at this time induced minute bleeding points. Rubbing with the blunt end of a glass rod also caused hemorrhage and these mechanical stimuli applied to such an area caused pain. Two of these small hemorrhagic lesions kept in contact with gastric juice for half an hour caused a sharp acceleration of acid secretion and concomitant hyperemia of the whole gastric mucosa which persisted for half an hour after submersion of the hemorrhagic lesions was discontinued. In this phenomenon may lie an explanation of the persistent hyperacidity regularly present in persons suffering from "gastritis" and peptic ulcer. The fact that the base of an ulcerated lesion constantly bathed in acid gastric juice stimulates acid secretion indicates that afferent impulses subserve this reflex without any resulting sensation. Pain probably would follow an adequate chemical stimulus. A small erosion on the peripheral edge of the mucosa lacking in mucus was exposed to the digestive action of gastric juice for four days, when it exhibited the typical punch-out appearance of a chronic peptic ulcer with well defined edges and a granulating base. Traction or pressure on this lesion caused dull gnawing pain. Throughout the four days the whole mucosa was relatively engorged and the rate of acid secretion was significantly elevated. At the end of the four days the ulcer and surrounding area were covered with a protective petrolatum dressing, and within three days healing was complete.

Toxoplasmic Encephalomyelitis—Koch and his associates describe the ocular changes in 6 cases of infantile toxoplasmic encephalomyelitis compare and arrange them in a sequence and point out in what way they may be unique and diagnostic. The essential lesion is a focal toxoplasmic chorioretinitis, bilateral and frequently multiple. Almost invariably the macular region in each eye is involved first, but more peripheral lesions often occur. The remaining portion of the retina and the vasculature are normal. Toxoplasmic chorioretinitis is an important diagnostic feature of infantile toxoplasmic encephalomyelitis and it first suggested the presence of the disease in 4 of the 6 cases presented. Toxoplasmic chorioretinitis must be differentiated ophthalmoscopically from pseudoglioma, intraocular tumors, traumatic birth lesions, hereditary cerebromacular degeneration and congenital developmental defects. The diagnostic intraocular lesions in infants and children are severe and extensive focal chorioretinal lesions, bilateral involvement of the macular region, peripheral involvement of one or more quadrants of the retina and choroid, punched out appearance of large and small lesions in the late phase, massive chorioretinal degeneration associated congenital ocular defects, rapid development of sequential optic nerve atrophy and usually a constant clarity of the media. The pathologic changes are necrotizing and inflammatory lesions in the retina and in the choroid similar to those found in the brain.

Tunica Vasculosa Lentis in Infants—Seven instances of a fibroblastic sheath behind the crystalline lens in both eyes of infants born about eight weeks prematurely are reported by Terry. The syndrome, which is usually bilateral, is composed of widespread primary and secondary manifestations related to persistence of the hyaloid artery and tunica vasculosa lentis, growth of embryonic connective tissue behind the lens and persistence of fetal fibrillar vitreous. It is usually observed four to six months after birth. The condition must be differentiated from retinoblastoma and congenital cataract. Glaucoma is an important complication. Treatment has been temporization, irradiation and closure of the hyaloid artery by diathermy. Complete excision of the membrane seems unwise, as pathologic specimens show that ciliary processes and retina adhere to the fibroplastic membrane. Intraocular hemorrhage and inflammation were found in the embryonic connective tissue of some pathologic specimens. A search for the essential etiologic factor or factors discloses that prematurity, often with twinning, is an important predisposing, but not invariably an essential, factor. The degree of prematurity appears to influence the nature of the involvement. The outstanding theoretical cause is a precocious increase in blood pressure brought on before the hyaloid artery and the tunica vasculosa lentis disappear, initiated by such normal factors as adaptation to extrauterine life or such abnormal factors as patent ductus arteriosus, dehydration or use of drugs. After the development of increased blood pressure hypertrophy of the hyaloid arterial system takes place, causing the fibrillar vitreous and the growth of supporting embryonic connective tissue to persist.

Plastic Film Treatment of Experimental Burns—Skinner and Wand compare the healing power anti-infective ability and other properties of five agents on the healing of experimentally produced wounds in rabbits. Data show that burns treated with two sulfonamide trichloroethylene burn fluids which result in a film when dry healed at least five days before those treated with tannic acid ten days before those treated with weak triple dye solution and forty days before those treated with strong triple dye solution. The anti-infective ability of strong triple dye solution is upheld but this fact does not overcome its adverse effect on healing time. Of the burn fluids the one that contained phemerol appeared to be of more value against infection. Weak triple dye or tannic acid was not as effective against infection as the other burn fluid. The burn fluids were more easily applied and gave a most satisfactory eschar which was easy to remove with warm saline solution without damage to the surface of the wound. All the other methods caused damage to granulation and epithelium when the eschar was removed.

Surgical Treatment of Pelvic Thrombophlebitis—Collins and his co workers present 3 cases of pelvic thrombophlebitis treated by ligation of the ovarian veins and the inferior vena cava. One case was postpartal, 1 followed an attempted criminal abortion and 1 followed a vaginal hysterectomy. The 3 patients have fully recovered and do not show any ill effects from the ligation. However the venous pressure in the lower extremities of the 3 is elevated, but there is no edema. The venous pressure has decreased in all as the interval from the date of the operation increases. This suggests that in the near future the venous pressure may return to or vary little from the normal. Following vena cava ligation, bilateral lumbar sympathetic block should be carried out to enhance the development of collaterals and to relieve any postoperative edema. If a patient feels faint and anxious while the block is being administered, the procedure should be discontinued immediately and attempted again in forty-eight hours. Roentgen examination of the chest is imperative in all cases, as emboli and infarction may be present without clinical symptoms.

Secondary Lesions of Syphilis—The use of the darkfield microscope on secondary dry or closed cutaneous syphilitic lesions can expedite treatment by obtaining a positive darkfield report instead of waiting for a positive serologic test. Agee reports 10 cases, 8 were seen in the New Orleans Health Department Clinic and 2 in the Tulane Clinic at Charity Hospital. For the test, the surface of the lesion must be abraded vigorously with a scalpel or dry gauze. If serum does not exude freely the area is squeezed to express sufficient material. The treponemes do not seem quite as active as those from open lesions perhaps because of the pressure exerted.

Meningitis Caused by the Higher Fungi—The four higher fungi causing meningitis that Skogland discusses are *Actinomyces*, *Blastomyces*, *torula* and *coccidioides*. Man apparently acquires actinomycotic meningitis from contact with infected hay or grain. Infection almost always occurs following a primary infection elsewhere in the body which spreads to the meninges by direct extension. The symptomatology of actinomycosis of the central nervous system depends on the several forms (meningitis, cerebral abscess and cerebellar abscess) that the pathologic reaction may take. The prognosis is poor in all cases terminate fatally. Therapy is entirely symptomatic, although empirically iodides may be prescribed. Infection with *Blastomyces* (*Oidiomyces*) is cutaneous with primary involvement usually on the face or hands and in a systemic form in which widespread dissemination of the organism occurs following invasion through the respiratory tract. The pathologic changes in the central nervous system are usually non-specific and closely resemble those associated with tuberculous meningitis. It is characterized by the usual symptomatic course lasting several months. There is no satisfactory therapy, and it is doubtful that roentgen therapy, excision and iodides have any beneficial effect after the meninges have been invaded. *Torula* meningitis is most common in male adults. The respiratory tract is the usual port of entry. Dissemination then takes place through the blood stream or lymph nodes when the central nervous system of at least half the cases is involved, other organs also are involved. The pathologic changes in the central nervous system are variable and the symptomatology varies with their nature and extent. There is no specific treatment

but symptomatic measures may produce temporary relief. *Coccidioides* granuloma, an endemic disease, occurs principally in the San Joaquin Valley, California. The fungus gains entrance through the lungs or the skin and subsequently is carried by the blood stream to other organs. In approximately 25 per cent of patients the meninges are involved. The disease occurs usually in adults and is more common in men. The pathologic changes vary with the duration of meningeal involvement. The symptoms are nonspecific but are similar to those of other chronic meningitides, often with superimposed evidence of internal hydrocephalus. *Coccidioides* meningitis always terminates fatally. Symptomatic therapy is the same as for other forms of meningitis. When localized spinal compression exists, laminectomy, in an attempt to remove granulomatous tissue, may be justified.

Ligation of Patent Ductus Arteriosus—Humphreys obliterated surgically a patent ductus arteriosus eight times in 7 children between 9 and 13 years of age. Roentgen, electrocardiographic and electrostethographic studies aided in proving the diagnosis. In several children one or more of the usual diagnostic criteria were absent, yet a patent ductus was always found. A low diastolic pressure was the most consistent observation. Associated skeletal anomalies were present in 3 and a congenital squint and torticollis in 1. Six ligations were carried out because of systemic effects of the mechanical circulatory abnormality and two to overcome subacute bacterial blood stream infection which had resisted adequate sulfonamide therapy. There were no postoperative deaths. The operation overcame the mechanical circulatory symptoms of 4 patients and the improvement has been maintained for twenty-eight, twenty-two, twenty and seventeen months, respectively. In 1 the patency recurred, apparently the result of cutting through the ligature, this was subsequently ligated successfully. In 1 the result is uncertain. In the 2 in whom infection was present at the time of operation, subsequent blood cultures have not shown organisms and the patients are conspicuously improved six and seven months after operation. In the year that has elapsed since the article was written, all but 1 of the patients continue in good health, the 1 in whom the result was uncertain died of complications arising from a postoperative aneurysm of the ductus. Nine additional patients have since been operated on without operative mortality. Five, operated on because of systemic symptoms, have shown moderate to pro-

nounced benefits. Four were operated on because of subacute blood stream infection, 1 has been free of infection for nine months, 1 died two months after operation of bacterial endocarditis due to an associated interventricular septal defect, 1 is living six months after operation with persistent murmur and subacute blood stream infection and 1 is in the postoperative period.

Serum and Plasma in Shock—On the basis of their experience with shock in dogs produced by graded hemorrhage, Levinson and his associates feel that concentrated blood protein solutions must be used circumspcctly, especially in dehydrated individuals. Concentrated plasma or serum was less effective in alleviating shock and in maintaining life thereafter than was normal plasma or serum. The state of hydration was an extremely important factor in the ability of an animal to withstand shock and its response to therapy. A more profound state of shock developed in dehydrated animals. Their response to plasma or serum infusion, and particularly to concentrated solutions, was decidedly poorer than that of normal animals. Therefore when concentrated plasma or serum is administered, particularly to dehydrated individuals, the degree and duration of improvement are apt to be incomplete and transient. If only concentrated serum or plasma is available additional normal plasma or saline solution should be administered at the earliest possible moment. The amount of citrate contained in plasma may be sufficient to produce tetany if large amounts are administered rapidly.

Surgical Excision of Hamartoma in Infant—Benson and Penberthy report the successful and complete excision of a primary encapsulated tumor (hamartoma) of the liver in an infant of 7 months. Three months after discharge the infant was in excellent health. All such infants deserve exploratory laparotomy because, in spite of the fact that hepatic tumors in them carry a poor prognosis occasionally a benign tumor will be found. Hamartoma of the liver can be considered benign because it is well encapsulated, it has embryonal characteristics, it does not tend to invade neighboring tissue, no mitotic figures are found microscopically, metastasis does not occur and symptoms are due to the progressive displacement of neighboring structures by the tumor.

Peritoneal Response to Sulfonamides—Throckmorton studied the peritoneal response of albino rats to crystalline sulfonamide compounds, with special regard to the drugs possible effects on the local peritoneal defense mechanism. The animals withstood laparotomy very well. Peritoneal fluid was obtained in all instances by puncture. The drugs, 1 Gm per kilogram of weight implanted intraperitoneally at laparotomy, were sulfanilamide, sulfathiazole, sulfapyridine, sulfadiazine, sulfamethyldiazine and sulfanilylguanidine. Each of them produced some peritoneal reaction, cellular changes in the peritoneal fluid. These reactions are nonspecific and depend on a foreign body reaction of the tissues to the drug and on the innate irritant properties of some of the compounds. The response produced by the rapidly dissolving and inert sulfanilamide is meager, but that initiated by sulfapyridine is so violent that masses of drug are walled off from the general peritoneal cavity. Between these two responses is the cellular response of sulfathiazole, which is the equal of peritoneal vaccination. The ability of sulfathiazole to enhance the local cytologic defense mechanism, and the prolonged bacteriostatic property of sulfonamides, would seem to make it the sulfonamide compound of choice for intraperitoneal use. The actual killing and disposal of the attenuated bacteria are performed by the local cellular defense mechanism. The vigorous response of sulfapyridine causes it to be walled off from the general peritoneal cavity so rapidly as to reduce even its effectiveness as a bacteriostatic agent.

Staphylococcus Aureus in Milk of Nursing Mothers—Duncan and Walker tried to determine the incidence of *Staphylococcus aureus* in the intestine and throat of morbid and healthy newborn infants and in the milk of their mothers, from January 1940 to January 1941 more than 2,500 swabs of materials from these sources were examined. During the last eight months, when the work was interrupted by enemy action, 82 mothers and their babies were examined at one hospital, from only 3 of the 82 mothers or babies *Staphylococcus aureus* was not obtained. At another hospital, situated approximately 26 miles away, the incidence was less but still high. With few exceptions the coccus cultivated from the mother's milk was of the same kind as that from the baby's throat and usually also that from its rectum. In a series of 87 mothers and their babies the coccus was found first in the throats of 33 babies, first in the milk of 15 mothers and simultaneously in the mother and the baby in 39 instances. The presence of *Staph. aureus* was not associated with any serious disturbance of health, although the types of the organism identified were also found in some inflammatory and suppurative conditions in the women and their babies. The transmission of the staphylococci among the babies and from the baby to the mother may also be effective for the transmission of more virulent or toxigenic staphylococci, with graver consequences.

Anemia in Women and Children on Wartime Diets—Between September 1941 and January 1942 Wills and her co-workers estimated the hemoglobin of 544 women and 530 children by the Haldane method. The values obtained were compared with those of similar groups investigated before the war. The mean hemoglobin value for the women was 89.5 per cent, the range was from 56 to 120 per cent. The mean is similar to that obtained by Davidson and his associates in 1937 for a group of nulliparous women from the poorest class in Aberdeen. In 1931 the mean figure of 98.3 per cent was obtained by Price-Jones for 100 supposedly healthy nurses and women students, and a mean figure of 100.5 per cent for 116 women was obtained by Jenkins and Don in 1933. The hemoglobin percentage was below 90 in 54 per cent and below 80 in 10 per cent of the present authors' subjects. In Price-Jones's series no hemoglobin value was below 90 per cent, though in Jenkins and Don's series it was below 90 in 9 per cent and below 80 in 1 per cent. The curve of the mean hemoglobin values of 364 children between 6 months and 5 years of age at successive ages approximates the curves of ten years ago for British children not receiving medicinal iron. The average hemoglobin level at 6 to 12 months was 75.4 per cent, between 1 and 2 years 72.8 per cent and thereafter it gradually rose until between 4 and 5 years it reached 81.8 per cent. The lowest levels were among children less than 2 years of age. The hemoglobin level of these children must be considered pathologically low. The incidence of severe anemia was lower in a welfare group of children than in other groups and was highest among children in residential nurseries. The mean

hemoglobin level of 90 school children from 5 to 13 years of age was 80.3 per cent (about 10 per cent lower than Davidson's 1935 mean for poor children in Aberdeen) of 38 school children from 13 to 15 it was 89.3 per cent and of 38 adolescent girls working at a factory it was 98.7 per cent. The authors believe that the general lowering of the mean hemoglobin value of older subjects and the low curves obtained for the younger children are the expression of a nutritional anemia and that iron deficiency is one important etiologic factor, but that other factors have also played a part in the production of this anemia. It is probable that among women and school children other dietetic deficiencies are implicated, and that in nurseries a high incidence of infection has increased the incidence and severity of an anemia primarily due to an iron deficiency. The bearing of this anemia on the health of the nation is of sufficient importance to call for immediate official action and further investigation.

Active Immunization Against Tetanus—Boyd and MacLennan record the incidence of tetanus during the first two years of war in the Middle East and assess the part played by active and passive immunization in its prevention. Despite the fact that *Clostridium tetani* is relatively rare in samples of soil in the Middle East, it is found in wounds. In 214 cultures of wounds received from different hospitals *C. tetani* was found in 18 (8.4 per cent). In another hospital swabs from 494 cases revealed one or more species of clostridium in 66, including 20 terminal spored anaerobes, 2 of these were *C. tetani*. In the period under review 18 cases of clinical tetanus have been reported and the evidence in favor of active immunization appears to be definite. Of the 18 5 were in men who had been actively immunized 4 with two doses and 1 with three doses. However, none of the 5 received the 3,000 prophylactic units of tetanus antitoxin after being wounded. Of these 5 2 recovered. Of the 13 patients who had not been immunized 1 received a single dose of 1 cc of tetanus toxoid three and a half months before he was wounded, 3 were Italian prisoners and 1 an Eritrean prisoner regarding whose inoculation history nothing is known. There were six fatalities. It is known that 3 of these 6 received prophylactic tetanus antitoxin. None of the 7 patients who recovered seem to have received any prophylactic tetanus antitoxin. There was a general tendency toward a long incubation period in all the patients. This cannot be attributed to antitoxin treatment but may in some way be related to effective surgical removal of all but the most trivial foci of infection. Evidently the protection afforded by active immunization has its 'ceiling'. It appears capable of inactivating toxin from a wound from which the bulk of necrotic tissue has been removed, but not from one forming massive quantities of toxin in extensive necrotic areas. The closed plaster technique was not without danger to 1 of the patients: a mass of necrotic tissue was unsuspected until symptoms supervened when it was too late for benefit to ensue from its removal. The little that is known about tetanus in the British Expeditionary Force in France during 1939-1940 reveals 8 cases among the unprotected 10 per cent and none among the 90 per cent actively immunized.

Zinc Peroxide in Clostridium Welchii Infection—McIntosh and Selbie found that the local application of zinc peroxide was apparently of no value in preventing the development of experimentally produced *Clostridium welchii* infection in mice when the organism had invaded the tissues. Proflavine was of greater value than sulfanilamide and was at least as good as sulfathiazole in the local prophylaxis and treatment; therefore its use as a wound dressing should be further explored. Penicillin injected at the site of infection within three hours of infection was a powerful prophylactic and in this respect it was superior to proflavine and the sulfonamides.

- New Roentgenologic Method of Topographic Marking and Localization. P. J. Coletos and L. H. Coletos LaFay — p. 151

Sterilization of Drinking Water—The procedure suggested by Violle and Seigneurin has the advantage of being able to sterilize extremely contaminated water in fifteen minutes and does not require filtration. The authors found that 1 liter of water containing 12 billion of *Escherichia coli* is sterilized in fifteen minutes by the addition of 1 mg. of potassium permanganate and 1.5 Gm. of citric acid. Typhoid, paratyphoid A and B, dysentery bacilli and cholera vibrios are destroyed by the same dose. The advantage of the method lies in the fact that the amount of permanganate used is only one fiftieth of that utilized in other procedures of water sterilization. Decolorization by hyposulfite is unnecessary, because it takes place spontaneously in about fifteen minutes. Filtration is superfluous, because the quantity of manganese oxide formed is harmless. The water so treated is rather acid (pH about 4.2). In order to render it more potable it can be neutralized with sodium bicarbonate. The method can be simplified by combining 1.5 Gm. of citric acid and 1 mg. of potassium permanganate in a tablet with 0.5 Gm. of lactose as an excipient. This tablet, when placed in water, produces first a rose color and then a yellowish brown, but at the end of fifteen minutes the water is again transparent. At this time a tablet containing 2 Gm. of sodium bicarbonate and 0.25 Gm. of lactose is added. This effects neutralization of the citric acid and a slight liberation of carbonic gas. The simplicity, efficacy and rapidity make the method valuable for explorers, in floods, epidemics, wars and whenever industrial purification is inadequate or nonexistent. The second procedure has the advantage of requiring only a single tablet which produces its effect in twenty minutes. The composition of this tablet is potassium permanganate 0.001 Gm., citric acid 0.02 Gm., potassium iodide 0.02 Gm., potassium iodate 0.01 Gm. and lactose 0.15 Gm. This form of sterilization (single tablet) can be used whenever, as is usually the case, the water does not contain more than 1 billion of *Escherichia coli* or of typhoid bacilli.

- *Surgical Treatment of Cancer of Esophagus. R. C. Ferrari — p. 545

Cystostomy for Rupture of Urethra—Roccatagliata analyzes 35 cases of rupture of the urethra. He concludes that: 1. Diagnosis of the existence, localization and severity of a urethral rupture is to be based exclusively on the clinical symptoms and their interpretation. 2. The symptoms determine the treatment to be employed. 3. Early endourethral exploration is not to be practiced. 4. Urinary retention demands an immediate cystostomy. 5. Large hematomas should be incised and drained, following hypogastric evacuation of the urine, however, in case of small hematomas an expectant attitude is justified. 6. Hemorrhage from the urethra does not endanger life and does not require local treatment. Urethral ligation and catheterization have been discarded. 7. Urethral repair by suture should be postponed for at least six weeks. 8. A permanent endourethral tube should never be left in contact with the suture. 9. Endourethral examination should not be done too soon after trauma or suture. It should not be practiced before inflammation of the scar has completely subsided, because the resulting irritation would produce hypertrophy, which would lead to

stenosis of the passage. Dilations should not be begun before six weeks have elapsed. 10. In cases in which extensive destruction prevents the approximation of the two ends, their suture to the perineum and a secondary urethral reconstruction, according to Guyon Leguay, is recommended (perineal urethrostomy). 11. Early hypogastric cystostomy is most important in the surgical treatment of urethral ruptures; it prevents infection and urinary continuation of the lesion and contributes much to successful repair. It made possible elimination of the permanent catheter.

Surgical Treatment of Cancer of Esophagus—Successful extirpation of cancer of the esophagus was performed in 1913. The 2 cases reported in that year remained a bold surgical adventure for a long time. Up to 1930 only 3 similar successes were reported. Recent advances in endothoracic surgery, according to Ferrari, led to successful extirpation of esophageal cancers. Garlock, Churchill and Plummer have reported impressive series of cases. Since 1940 extirpation of cancer of the thoracic esophagus has been done a number of times in Argentina; the first 2 of these patients are still well and now there are 5 more who have been saved from death by this procedure. The operation is not necessarily grave; its mortality is low and would be still lower if early operation were the rule. Two factors interfere with the successful surgical treatment of cancer of the esophagus: (1) The patient asks for medical advice relatively late and (2) the physician as well as the patient is hesitant in accepting the operation. Many physicians lack confidence in the merits of the operation, their attitude being much the same as that which prevailed thirty years ago with regard to rectal cancer. Today extirpation of rectal cancer is no longer disputed. In some respects extirpation of esophageal cancer is less difficult than that of rectal cancer. The esophagus is less symptomatic and less vascular, and diffuse infection of the pleural cavity is avoided much more readily and better tolerated than that of the peritoneal cavity. Early clinical manifestations which permit earlier diagnosis, lesser malignancy and lesser tendency to metastasization are other factors that make the problem of esophageal cancer less serious than that of rectal cancer. Ferrari stresses that the possibility of esophageal cancer should be considered in the presence of dysphagia. Such patients should be referred at once to a center where thorough examination by roentgenography, esophagoscopy and biopsy is possible.

Revista de Neuro-Psiquiatria, Lima

5 315 431 (Sept) 1942 Partial Index

- *Acute Cerebral Edema After Neosarsphenamine Therapy. L. D. Espejo and J. Voto Bernales — p. 315
- Experimental Catlepsy Produced by Nicotine. C. Gutierrez Noriega — p. 323

Acute Cerebral Edema—According to Espejo and Voto Bernales acute cerebral edema after neosarsphenamine therapy is a rare but a grave complication. The condition may develop as a reaction of the nervous tissue to neosarsphenamine when the injection is given too rapidly and in the presence of an individual predisposition, as well as in certain diseases and infections. A constitutional vasomotor instability, especially in young persons, hyperthyroidism, toxic goiter, thymolymphatic disorders and alcoholism are the most frequent predisposing factors. The author reports 3 cases. The total dose reached before the appearance of acute cerebral edema was 0.9 Gm. or more. The symptoms appeared after the third injection in all of the cases. The prodromal symptoms consisted of acute headache, vomiting, epigastric pain, diarrhea, insomnia and incapacity for work. The acute symptoms were those of the apoplectic, convulsive and pseudoepileptic type. There was definite dissociation of the albumin component of the cerebrospinal fluid and increase in glycogen in all cases. The precipitation curve of the colloidal benzoic test was carried out in only 1 case. It was of the left (parenchymal) type. Two of the patients aged 28 presented vasomotor disorders. One was cured. The authors believe that acute cerebral edema after neosarsphenamine therapy is a local allergic phenomenon.

Book Notices

Manual of Oxygen Therapy Techniques Including Carbon Dioxide Helium and Water Vapor By Albert H. Andrews Jr. M.D. Director Oxygen Therapy Department and Assistant Attending Otolaryngologist St. Luke's Hospital Chicago. Cloth. Price \$1.75. Pp. 191 with 33 illustrations. Chicago: Year Book Publishers Inc. 1943.

In the preface Dr. Andrews points out that "correct administration of oxygen therapy requires attention to many details which are overlooked so frequently that a manual of this type has been considered necessary." The result appears to be an excellent compendium of a considerable amount of useful information not otherwise readily available to the technician, the nurse or even the physician who has occasion to operate oxygen therapy equipment. It should be valuable to those specializing in inhalation therapy. Except for a short section on the physiology of respiration and rationale of gas therapy the manual has been limited to a discussion of the mechanical aspects and recommended safety precautions of administering oxygen. Instructions and descriptions are supplemented by numerous illustrations and charts. The author has been quite thorough in his description of techniques for operating a wide variety of modern and generally accepted types of equipment and in many instances presents special instructions which are required for specific makes of equipment. The book also includes operating data useful to those interested in carbon dioxide therapy, helium-oxygen therapy and water vapor therapy. Suggestions for handling administrative and clerical details of oxygen therapy in hospitals are doubtless based on the author's own practical experience and should prove extremely valuable to others. A chapter is devoted to a description of the organization and activities of an oxygen therapy department within the hospital. Another chapter describes various charts and records used for the recording of patients' progress and for the accumulation of statistical results of gas therapy. There are also chapters containing descriptions of and suggestions affecting the purchase of therapeutic gases, pressure regulating devices and gas piping systems as well as useful hints on the handling and maintenance of oxygen equipment. Though already widely used in the treatment of many different diseases and conditions, oxygen therapy seems on the way to still greater use, and this book should contribute much toward its effective, safe and economical application, without which oxygen therapy becomes merely a medical gesture.

Biochemistry and Morphogenesis By Joseph Needham F.R.S. Cloth. Price \$12.50. Pp. 787 with 328 illustrations. New York: Macmillan Company. Cambridge: University Press. 1942.

The printing of this book in Great Britain amid the disruption caused by a world war shows definitely that the British set a high and proper value on the maintenance of facilities for publishing an important scientific work not directly related to the war effort. The book is a painstaking analysis of the biochemistry of the morphogenic hormones in a search for a physicochemical causal basis for morphogenesis. As such it comes as a suitable supplement to the author's earlier three volume *Chemical Embryology*, in which the discussion was limited largely to the consideration of paracrystalline aggregates, colloidal nucleoli, fibrous macromolecules and protein structure and the study of the chemical changes which go on in embryonic development.

Of the three parts into which the present book is divided, part I is devoted to the morphogenic substratum, including under this head such topics as the constitution of the egg of invertebrates and of vertebrates, particularly the hen's egg; environmental factors, mortality curves, embryonic nutrition and the mammalian placenta. Part II, dealing with the morphogenic stimuli, occupies the major part of the book. At this point the author's apology "on the part of one whose training was not morphological" seems quite unnecessary in view of the author's adequate presentation of the morphologic background. This part of the book discusses the general concepts of causal morphology and the extent to which biochemistry can be utilized as a source of causal factors in development. The evidence for the presence of organizers under various circumstances is fully

treated, including the relation of organizers to genes and their possible role in carcinogenesis. Of the special techniques employed, mention should be made of the successful use of a refinement of the cartesian diver manometer in the determination of oxygen consumption in small pieces of embryonic tissue. Part III, concerned with the morphogenic mechanisms, deals with the facts and theories of dissociability, heterauxesis, respiration metabolism and polarity. The basic aim of the book as a whole is to show that organizing relations exist at the molecular and paracrystalline levels as well as at the morphologic levels that chemistry and morphology are closely related. The usefulness of the book is heightened by its clear concise English and by the inclusion of a glossary of terms, a bibliography of seventy pages, a general index and separate indexes of animals, plants and genes.

Radio Broadcasting: A Critical Study of Health Education by The Medical Profession. The Official Health Organizations. The Voluntary Health Agencies. Paper. Pp. 81. New York: New York Academy of Medicine. 1942.

This study was made under the supervision of the Committee on Medical Information of the New York Academy of Medicine with the aid of a grant from the Rockefeller Foundation, Division of Humanities. The study is divided into a chapter on background facts, one on opinions of experts gathered by personal interview, a chapter on critical study of the radio health education program of the New York Academy of Medicine called "Highways to Health," an interpretation of the opinions expressed by the experts, an evaluation of the data gathered from the study of the academy broadcasts, a chapter on the objectives of radio health education, one on techniques in radio, one on the radio audience, one on radio and the printed word, one on the economics of radio health education, and a summary and conclusions.

The author presumably considers that, in general health education by radio is not a success but that it could be made successful. This conclusion is based on the opinions of the experts whose names are listed in an appendix and who constitute in truth an impressive list of personalities in medicine, public health, radio and educational circles. Impressive as this list is, it adds nothing to the report because the reader cannot tell what any of these eminent persons actually contributed, since each is identified only by one star, two stars or three stars representing respectively the opinion that radio in health education is virtually valueless, that radio in health education does fairly well but could do better than radio as an instrument of health education is doing very well indeed. If an eminent authority in public health with little or no radio experience is to be accepted at the same value as one who knows much about radio and little about health education such a classification might be acceptable but any one who is experienced in both radio and health education will not be satisfied by any such ambiguity.

The author is particularly critical of those who believe that it is necessary to attract audiences by radio presentations which have some of the features of commercial programs, namely entertainment. In the introduction he refers contemptuously to this idea "cap and bells make a poor miter for the teacher's toga." Throughout the report he appears to be sharply critical of any one who would attempt to lure the radio audience with any of the bait to which this audience is so susceptible. Although he points out that studies by Lazarsfeld of the Columbia School of the Air indicate that the lower the scale of culture in the home the greater the amount of radio listening, he scorns the idea of appealing to these nonintellectual listeners with the daytime serials so dear to their hearts. He overlooks completely the fact that, no matter how excellent may be the educational material presented, it will be of little use if the only audience is the little man who wasn't there.

The purpose of drama, Dr. Schultz totally fails to recognize, is not to convey health information but to make reasonably sure that some one will be listening when the health education is conveyed. Dramatization will accomplish this, is demonstrated by the radio programs of the American Medical Association to which audience response when asked is so great that it can seldom be asked for fear of overwhelming the resources available for handling and replying to audience mail.

Water H Violle and R Seigneurin—p 150
- New Roentgenologic Method of Topographic Marking and Localization
P J Coletso and L H Coletso LaFay—p 151

Sterilization of Drinking Water—The procedure suggested by Violle and Seigneurin has the advantage of being able to sterilize extremely contaminated water in fifteen minutes and does not require filtration. The authors found that 1 liter of water containing 12 billion of *Escherichia coli* is sterilized in fifteen minutes by the addition of 1 mg of potassium permanganate and 15 Gm of citric acid. Typhoid, paratyphoid A and B, dysentery bacilli and cholera vibrios are destroyed by the same dose. The advantage of the method lies in the fact that the amount of permanganate used is only one fiftieth of that utilized in other procedures of water sterilization. Decolorization by hyposulfite is unnecessary, because it takes place spontaneously in about fifteen minutes. Filtration is superfluous, because the quantity of manganese oxide formed is harmless. The water so treated is rather acid (pH about 4.2). In order to render it more potable it can be neutralized with sodium bicarbonate. The method can be simplified by combining 15 Gm of citric acid and 1 mg of potassium permanganate in a tablet with 0.5 Gm of lactose as an excipient. This tablet, when placed in water, produces first a rose color and then a yellowish brown, but at the end of fifteen minutes the water is again transparent. At this time a tablet containing 2 Gm of sodium bicarbonate and 0.25 Gm of lactose is added. This effects neutralization of the citric acid and a slight liberation of carbonic gas. The simplicity, efficacy and rapidity make the method valuable for explorers, in floods, epidemics, wars and whenever industrial purification is inadequate or nonexistent. The second procedure has the advantage of requiring only a single tablet which produces its effect in twenty minutes. The composition of this tablet is potassium permanganate 0.001 Gm, citric acid 0.02 Gm, potassium iodide 0.02 Gm, potassium iodate 0.01 Gm and lactose 0.15 Gm. This form of sterilization (single tablet) can be used whenever, as is usually the case, the water does not contain more than 1 billion of *Escherichia coli* or of typhoid bacilli.

- *Surgical Treatment of Cancer of Esophagus R C Ferrari—p 545

Cystostomy for Rupture of Urethra—Roccatiglioni analyzes 35 cases of rupture of the urethra. He concludes that: 1. Diagnosis of the existence, localization and severity of a urethral rupture is to be based exclusively on the clinical symptoms and their interpretation. 2. The symptoms determine the treatment to be employed. 3. Early endourethral exploration is not to be practiced. 4. Urinary retention demands an immediate cystostomy. 5. Large hematomas should be incised and drained, following hypogastric evacuation of the urine, however, in case of small hematomas an expectant attitude is justified. 6. Hemorrhage from the urethra does not endanger life and does not require local treatment. Urethral ligation and catheterization have been discarded. 7. Urethral repair by suture should be postponed for at least six weeks. 8. A permanent endourethral tube should never be left in contact with the suture. 9. Endourethral examination should not be done too soon after trauma or suture. It should not be practiced before inflammation of the scar has completely subsided, because the resulting irritation would produce hypertrophy, which would lead to

stenosis of the passage. Dilations should not be begun before six weeks have elapsed. 10. In cases in which extensive destruction prevents the approximation of the two ends, their suture to the perineum and a secondary urethral reconstruction, according to Guyon-Legueu, is recommended (perineal urethrostomy). 11. Early hypogastric cystostomy is most important in the surgical treatment of urethral ruptures, it prevents infection and urinary contamination of the lesion and contributes much to successful repair. It made possible elimination of the permanent catheter.

Surgical Treatment of Cancer of Esophagus—Successful extirpation of cancer of the esophagus was performed in 1913. The 2 cases reported in that year remained a bold surgical adventure for a long time. Up to 1930 only 3 similar successes were reported. Recent advances in endothoracic surgery, according to Ferrari, led to successful extirpation of esophageal cancers, Garlock, Churchill and Plummer have reported impressive series of cases. Since 1940, extirpation of cancer of the thoracic esophagus has been done a number of times in Argentina, the first 2 of these patients are still well and now there are 5 more who have been saved from death by this procedure. The operation is not necessarily grave, its mortality is low and would be still lower if early operation were the rule. Two factors interfere with the successful surgical treatment of cancer of the esophagus: (1) The patient asks for medical advice relatively late and (2) the physician as well as the patient is hesitant in accepting the operation. Many physicians lack confidence in the merits of the operation, their attitude being much the same as that which prevailed thirty years ago with regard to rectal cancer. Today extirpation of rectal cancer is no longer disputed. In some respects extirpation of esophageal cancer is less difficult than that of rectal cancer. The esophagus is less septic and less vascular, and diffuse infection of the pleural cavity is avoided much more readily and better tolerated than that of the peritoneal cavity. Early clinical manifestations which permit earlier diagnosis, lesser malignancy and lesser tendency to metastatization are other factors that make the problem of esophageal cancer less serious than that of rectal cancer. Ferrari stresses that the possibility of esophageal cancer should be considered in the presence of dysphagia. Such patients should be referred at once to a center where thorough examination by roentgenography, esophagoscopy and biopsy is possible.

- *Acute Cerebral Edema After Neosphenamine Therapy L D Espejo and J Voto Bernales—p 315
- Experimental Cataplexy Produced by Nicotine C Gutierrez Noriega—p 323

Acute Cerebral Edema—According to Espejo and Voto Bernales acute cerebral edema after neosphenamine therapy is a rare but a grave complication. The condition may develop as a reaction of the nervous tissue to neosphenamine when the injection is given too rapidly and in the presence of an individual predisposition as well as in certain diseases and infections. A constitutional vasomotor instability, especially in young persons, hyperthyroidism toxic goiter, thymolymphatic disorders and alcoholism are the most frequent predisposing factors. The author reports 3 cases. The total dose reached before the appearance of acute cerebral edema was 0.9 Gm or more. The symptoms appeared after the third injection in all of the cases. The prodromal symptoms consisted of acute headache, vomiting, epigastric pain, diarrhea, insomnia and incapacity for work. The acute symptoms were those of the apoplectic convulsive and pseudoepileptic type. There was definite dissociation of the albumin component of the cerebrospinal fluid and increase in glycogen in all cases. The precipitation curve of the colloidal benzoic test was carried out in only 1 case. It was of the left (parenchymal) type. Two of the patients aged 28 presented vasomotor disorders. One was cured. The authors believe that acute cerebral edema after neosphenamine therapy is a local allergic phenomenon.

Book Notices

Manual of Oxygen Therapy Techniques Including Carbon Dioxide Helium and Water Vapor. By Albert H. Andrews Jr. M.D. Director Oxygen Therapy Department and Assistant Attending Otolaryngologist St. Luke's Hospital Chicago. Cloth. Price \$1.75. Pp. 181 with 33 illustrations. Chicago: Year Book Publishers Inc. 1943.

In the preface Dr. Andrews points out that "correct administration of oxygen therapy requires attention to many details which are overlooked so frequently that a manual of this type has been considered necessary." The result appears to be an excellent compendium of a considerable amount of useful information not otherwise readily available to the technician, the nurse or even the physician who has occasion to operate oxygen therapy equipment. It should be valuable to those specializing in inhalation therapy. Except for a short section on the physiology of respiration and rationale of gas therapy the manual has been limited to a discussion of the mechanical aspects and recommended safety precautions of administering oxygen. Instructions and descriptions are supplemented by numerous illustrations and charts. The author has been quite thorough in his description of technics for operating a wide variety of modern and generally accepted types of equipment and in many instances presents special instructions which are required for specific makes of equipment. The book also includes operating data useful to those interested in carbon dioxide therapy, helium-oxygen therapy and water vapor therapy. Suggestions for handling administrative and clerical details of oxygen therapy in hospitals are doubtless based on the author's own practical experience and should prove extremely valuable to others. A chapter is devoted to a description of the organization and activities of an oxygen therapy department within the hospital. Another chapter describes various charts and records used for the recording of patients' progress and for the accumulation of statistical results of gas therapy. There are also chapters containing descriptions of and suggestions affecting the purchase of therapeutic gases, pressure regulating devices and gas piping systems as well as useful hints on the handling and maintenance of oxygen equipment. Though already widely used in the treatment of many different diseases and conditions, oxygen therapy seems on the way to still greater use, and this book should contribute much toward its effective, safe and economical application, without which oxygen therapy becomes merely a medical gesture.

Biochemistry and Morphogenesis. By Joseph Needham F.R.S. Cloth. Price \$12.50. Pp. 787 with 328 illustrations. New York: Macmillan Company, Cambridge: University Press. 1942.

The printing of this book in Great Britain amid the disruption caused by a world war shows definitely that the British set a high and proper value on the maintenance of facilities for publishing an important scientific work not directly related to the war effort. The book is a painstaking analysis of the biochemistry of the morphogenic hormones in a search for a physicochemical causal basis for morphogenesis. As such it comes as a suitable supplement to the author's earlier three volume *Chemical Embryology*, in which the discussion was limited largely to the consideration of paracrystalline aggregates, colloidal micelles, fibrous macromolecules and protein structure and the study of the chemical changes which go on in embryonic development.

Of the three parts into which the present book is divided, part I is devoted to the morphogenic substratum including under this head such topics as the constitution of the egg of invertebrates and of vertebrates, particularly the hen's egg, environmental factors, mortality curves, embryonic nutrition and the mammalian placenta. Part II, dealing with the morphogenic stimuli, occupies the major part of the book. At this point the author's apology "on the part of one whose training was not morphological" seems quite unnecessary in view of the author's adequate presentation of the morphologic background. This part of the book discusses the general concepts of causal morphology and the extent to which biochemistry can be utilized as a source of causal factors in development. The evidence for the presence of organizers under various circumstances is fully

treated, including the relation of organizers to genes and their possible role in carcinogenesis. Of the special technics employed, mention should be made of the successful use of a refinement of the cartesian diver manometer in the determination of oxygen consumption in small pieces of embryonic tissue. Part III, concerned with the morphogenic mechanisms, deals with the facts and theories of dissociability, heterauxesis, respiration, metabolism and polarity. The basic aim of the book as a whole is to show that organizing relations exist at the molecular and paracrystalline levels as well as at the morphologic levels, that chemistry and morphology are closely related. The usefulness of the book is heightened by its clear, concise English and by the inclusion of a glossary of terms, a bibliography of seventy pages, a general index and separate indexes of animals, plants and genes.

Radio Broadcasting: A Critical Study of Health Education by The Medical Profession. The Official Health Organizations. The Voluntary Health Agencies. Paper. Pp. 81. New York: New York Academy of Medicine. 1942.

This study was made under the supervision of the Committee on Medical Information of the New York Academy of Medicine with the aid of a grant from the Rockefeller Foundation, Division of Humanities. The study is divided into a chapter on background facts, one on opinions of experts gathered by personal interview, a chapter on critical study of the radio health education program of the New York Academy of Medicine called "Highways to Health," an interpretation of the opinions expressed by the experts, an evaluation of the data gathered from the study of the academy broadcasts, a chapter on the objectives of radio health education, one on technics in radio, one on the radio audience, one on radio and the printed word, one on the economics of radio health education, and a summary and conclusions.

The author presumably considers that in general health education by radio is not a success but that it could be made successful. This conclusion is based on the opinions of the experts whose names are listed in an appendix and who constitute in truth an impressive list of personalities in medicine, public health, radio and educational circles. Impressive as this list is, it adds nothing to the report because the reader cannot tell what any of these eminent persons actually contributed, since each is identified only by one star, two stars or three stars representing respectively the opinion that radio in health education is virtually valueless, that radio in health education does fairly well but could do better than radio as an instrument of health education is doing very well indeed. If an eminent authority in public health with little or no radio experience is to be accepted at the same value as one who knows much about radio and little about health education, such a classification might be acceptable, but any one who is experienced in both radio and health education will not be satisfied by any such ambiguity.

The author is particularly critical of those who believe that it is necessary to attract audiences by radio presentations which have some of the features of commercial programs, namely entertainment. In the introduction he refers contemptuously to this idea "cap and bells make a poor miter for the teacher's toga." Throughout the report he appears to be sharply critical of any one who would attempt to lure the radio audience with any of the bait to which this audience is so susceptible. Although he points out that studies by Lazarsfeld of the Columbia School of the Air indicate that the lower the scale of culture in the home the greater the amount of radio listening, he scorns the idea of appealing to these nonintellectual listeners with the daytime serials so dear to their hearts. He overlooks completely the fact that, no matter how excellent may be the educational material presented, it will be of little use if the only audience is the little man who wasn't there.

The purpose of drama, Dr. Schultz totally fails to recognize, is not to convey health information but to make reasonably sure that some one will be listening when the health education is conveyed. Dramatization will accomplish this, as demonstrated by the radio programs of the American Medical Association, to which audience response when asked is so great that it can seldom be asked for fear of overwhelming the resources available for handling and replying to audience mail.

The author would like to divide health agencies neatly into three groups, the voluntary health agencies whose primary purpose is to agitate and to campaign, the medical organizations whose function is to instruct from the heights of Olympus, and the health departments and other governmental agencies which can do a little of each. He believes that a medical society has no right to view with alarm, whereas a tuberculosis association or a health department may properly get excited about bad health conditions in the community. He divides the radio audience into numerous groups and goes so far as to advise that radio presentations should be aimed at specific groups rather than at wide audiences. Although he mentions the necessity for correlating radio with other health education activities he treats radio throughout as if it were expected to accomplish the whole job of health education by itself, whereas it is in fact merely an attention catching medium which serves its most important function by attracting attention of indifferent persons and stimulating in them a desire to know something more about a subject important to them though not previously interesting.

The author says that dramatization is unwieldy and costly and that it obscures the educational purpose in radio health programs. Properly handled dramatization does none of these things. It is not unwieldy and need not be costly if community cooperation and ingenuity are appropriately substituted for dollars. With the author's contention that much interview and conversation are but shoddy imitations of genuine give and take on the air, this reviewer is in hearty accord. With the author's statement that a good health talk is better than a poor dramatization there can be no honest disagreement. But the fact remains nevertheless that good radio dramatizations interwoven with information have attracted the attention of millions of listeners who would otherwise have given no attention whatever to health talks or even interviews.

The most important points in this study are those which concern the defects and limitations of radio presentations, especially radio talks. These have too often been hastily and carelessly prepared and poorly delivered. The apparent but fictitious "expensiveness" of radio broadcasting has led to indifference and neglect in the preparation of radio material as compared with the care and expense lavished on printed matter and visual aids in health education. The author's recommendation for community cooperation in radio broadcasting looking toward better coordination of the quantity, quality and proportion of radio material broadcast in a given community is sound.

There are numerous criticisms in the report which are leveled at individual abuses. Since these abuses are not general, such criticism should either have been omitted or made specific. A case in point is the following: "Some medical societies are putting on dramatic programs which burlesque and belie medical research and which attempt to persuade the public that the doctor is a sort of hybrid Horatius at the Bridge and the humble St. Francis." The accusation is leveled at medical societies in plural. This reviewer, who is reasonably familiar with the national situation, knows of but few such instances. Other medical societies not guilty of this sort of thing should not have the finger of scorn pointed at them.

Texto de bacteriología. Por los doctores Arturo Curbelo y Hernandez y Giraldo Insua y Cartaya profesores auxiliares y agregados de la Cátedra de bacteriología de la Escuela de medicina de la Universidad de La Habana. Cloth. Pp. 610 with illustrations. Habana, Cuba. M. V. Fresnoa. 1943.

This excellent book combines the usual subjects included in general bacteriology with those of infection and resistance. The book is written for students. The authors describe the subjects with great clarity according to established facts. The presentation is excellent, the printing is clear, most of the illustrations are new and the diagrams are didactic. The chapter on Rickettsia, probably the best, reveals familiarity with the subject, certainly not surprising, since typhus fever has been studied in Cuba since 1938.

One would like to see this book improved and enlarged in further editions. The reader may indulgently smile when in the listing of highlights in the history of bacteriology the authors quote the finding of bacillary dysentery in Cuba next to the discovery of sulfonamide compounds and the crystallization of tobacco mosaic virus, but this attitude may change in other

passages of the book. The question of size of filtrable viruses—which poses basic problems concerning their nature—is dismissed with the statement that for most of them it ranges between 20 and 40 millimicrons, the filtrability of tubercle bacilli is accepted without much discrimination, too much space is devoted to agglutinins, possibly just a word to designate a heterologous group of substances. Important phenomena such as the Shwartzman phenomenon are not mentioned.

The sources of the book are almost exclusively American and North American. Yet for the first time in a book on bacteriology the reader comes frequently across names and contributions from Latin America, some known, like Finlay's, others still obscure for most readers, like the group of Mexican and Cuban workers responsible for establishing the spirochetal etiology of Pinto's disease. In this respect the book is representative of the newer trends of scientific thought in Latin America, which in quest of information, is swinging from the old to the new continent.

Understand Your Ulcer. A Manual for the Ulcer Patient. By Burrill B. Crohn, M.D., F.A.C.S., Associate in Medicine, Gastro-Enterology, Mount Sinai Hospital, New York. Cloth. Price \$2.50. 1p. 199 with 19 illustrations. New York: Sheridan House, Inc. 1943.

In line with the present tendency to give the layman an opportunity to know something about many ailments, Dr. Crohn presents a short description of peptic ulcer. The well known role of acidity, the bad effects of excessive or even ordinary smoking, the influence of psychic upsets or mental strain, the tendency toward recurrence of the ulcer, seasonal influence, the part played by age and occupation and the clinical course are well described not alone for the layman but also for the physician. If any criticism should be leveled at the treatment of the subject it might be that too much attention has been placed on the description of the pathology and x-ray examination which are not well comprehended by the layman. The discussion of the various methods of treatment of ulcer is well presented and its value is enhanced by part II, which is an appendix on diets by Sylvia Brand, consulting dietitian. Here are mentioned lists of foods allowed and to be avoided and the manner of preparation of the diet adequate for treatment of ulcer. It would not be amiss for the practitioner to acquaint himself with this section of the book. The makeup of the book is excellent and its value improved by several illustrations. It can serve a good purpose for the layman and nurses or even for some physicians.

Sanitary Inspectors' Manual. Louisiana State Department of Health, New Orleans, La. [Including] Supplement I. Act 142 of 1936 as Amended by Act 19 of 1942. The State Food, Drugs and Cosmetic Act. Supplement II. Act No. 202 of 1942. Enrichment of Flour and Bread. Supplement III. Act No. 203 of 1942. Enrichment of Oleomargarine. Prepared 1942 by Ben Freeman, M.D. Paper. Pp. 3+0. 22. 8. 2 with illustrations. New Orleans, Louisiana: Fearless Printing Co. 1942.

For use of sanitary inspectors of the Louisiana State Department of Health, the author has compiled a manual covering every phase of the sanitarian's work. The chapters include bacteriology, bacteriology of water and milk, control of food and milk supplies, sewage disposal, food handling, meat control and the control of rodents and insect pests and of communicable diseases. There are sections on housing, vital statistics and numerous formulas. Special supplements cover the legislation of the state of Louisiana affecting the work of the sanitarian. A number of supplements are also included from official publications of the American Public Health Association. The work is so practical that its immediate application to the duties of the sanitarian is obvious. A similar publication for sanitarians in other states, modeled on this publication, will be well worth while.

Heating Your Home in Wartime for Comfort, Economy, Health. A Bulletin Prepared for Governor Harold E. Stassen by the Scientific Advisory Committee to Minnesota War Industries. Paper. Pp. 32 with 5 illustrations. St. Paul, Minnesota: Resources Commission. 1942.

This pamphlet contains information about heating the home. It is written in a popular style with brief descriptions of different methods for avoiding heat loss from structures and for saving fuel by modification of operating conditions. A brief discussion of comfort and health factors in relation to house heating is also included.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

COMMON COLD, ATYPICAL PNEUMONIA AND SULFONAMIDE ADMINISTRATION

To the Editor—For the past several months I have observed many cases of acute respiratory infection which did not conform with the ordinary chest cold that have been seen so frequently in the past. In talking with other physicians in this neighborhood I find that they also are experiencing this peculiar type of respiratory infection. One of the unusual things about these cases is that a large number of them are associated with moderate hemoptyses. It has been called to my attention that most of these cases in which hemoptyses occurred were also cases in which a sulfonamide drug had been administered. In view of this finding I am beginning to be curious as to the possibility of the drug being in some way responsible for the hemoptyses.

W L Howard MD Battle Creek Mich

ANSWER—In the absence of any details describing the acute infection of the respiratory tract referred to, which seems to differ from the ordinary "chest cold," one could guess that the query deals with the newly recognized syndrome called 'primary atypical pneumonia' or 'viral' pneumonia, which has assumed epidemic proportions in recent months particularly in military camps. However, hemoptysis, although it may occur, is not particularly characteristic of this infection. There is no reason to suppose that the use of sulfonamide compounds is connected with the spitting of blood in such cases, at least, no mention of it has as yet appeared in the literature. The question may be asked why sulfonamide compounds were given to such patients at all.

The query touches on the controversy concerning the use of sulfonamide compounds routinely for the common cold either in the hope of influencing the disease itself or to prevent the development of pneumonia. Convincing evidence has not yet appeared to show that the indiscriminate use of sulfonamide compounds is helpful in the common cold and all authors agree that they have no effect on the syndrome called viral pneumonia yet they are widely used for both conditions. In the state of present knowledge there is no justification for the use of chemoprophylaxis in colds to prevent pneumonia. In the first place only about 1 in 1,000 patients with colds develop clinical pneumonia, and not all pneumonias which so develop are amenable to chemotherapy. Thus far in the current season for example from 60 to 75 per cent of pneumonias have been of unknown cause. The mortality rate in these cases was nil even in those untreated with sulfonamide compounds. Secondly there is incomplete knowledge at present as to the incidence and degree of sensitization to sulfonamide compounds after they are given empirically in trivial diseases, which may cause a dangerous reaction if chemotherapy is given later for a really serious infection in which it is urgently needed. There are, no doubt certain selected cases of the common cold in which chemoprophylaxis seems to be indicated: (1) in severe cases with fever and symptoms which show a tendency to increase with increasing leukocytosis and evidence of spread into the bronchi and lungs, (2) when an epidemic of pneumococcal pneumonia or meningococcal meningitis coexists and, according to Spink (Use and Abuse of Chemotherapy, *Minnesota Med* 25:988 [Dec] 1942), (3) in patients who have valvular heart disease and (4) in obstetric patients who develop colds at or near term.

In the average case of the common cold an alert physician by clinical observation alone can usually decide whether or not to withhold chemotherapy until actual indication for its use arises. His judgment is greatly aided by roentgenography when available and by laboratory studies to discover the cause. With regard to the latter point it is evident from the studies of Faller, Quickel and Smith (*Pennsylvania M J* 46:339 [Jan] 1943) that physicians in general are deplorably indifferent. In their survey, attempts to discover the causative agent by which the selection of specific therapy can be controlled, were made in only 17 per cent of cases of pneumonia.

OZENA

To the Editor—A patient has ozena. Will you kindly send me the treatment for this condition?

A A Lepis Lieutenant M C A U S

ANSWER—There is no completely satisfactory or even simple answer to the query. First of all one must consider the numerous notions regarding the causation of ozena, if one means by that term an atrophic rhinitis accompanied by crusting and a

fetid odor. Cullom in a recent article mentions at least ten theories concerning etiology. Among these are:

- 1 Too great shortness and width of the nostrils
- 2 Purulent rhinitis of childhood
- 3 Purulent disease of the nasal accessory sinuses
- 4 Infection due to specific bacteria such as (a) *Bacillus mucosus* (Abel), (b) *Bacillus fetidus ozenae* (Hayek), (c) *Coccobacillus fetidus ozenae* (Perez). The following may be added (d) endocrine disturbances and vitamin deficiencies.

Each proponent of a theory bases his therapy in large part on what he considers to be the chief causative factors. This leads some to stress the treatment of a concomitant purulent sinusitis, others to the giving of various vitamins and still others to the use of various endocrine preparations. In this connection it may be wise to mention Crowe's warning that estrogenic injections and implants for the treatment of ozena in the young may cause harmful disturbances in the long bones and genitalia which outweigh any nasal benefits. Modern conservative treatment may be summed up as follows: Surgical procedures which aim to narrow the nasal passages should be reserved for those cases which resist all simpler measures. Purulent sinusitis should be searched for and if present should be handled according to accepted standards.

The patient's general health should be considered, the nasal cavities should be thoroughly cleansed in the office by the removal of crusts and secretion, and the patient may be instructed in the use at home of saline irrigations and douches. Following this some bland vegetable oil such as oil of sesame may be sprayed in the nose. Mineral oils should be avoided so as not to risk the possibility of lipid changes in the lungs. Iodine in glycerin in strengths varying from 1 to 5 per cent is used by many as drops in the nose or applied with a swab. Scarlet red as a 5 per cent ointment is recommended by some, and still others use 10 to 20 per cent dextrose solutions in glycerin as drops to abate the objectionable odor.

POSSIBLE LATE COMPLICATIONS OF ANAPHYLACTIC REACTION

To the Editor—A patient who has been a laborer all of his life now aged 65 has been in good health as far as he is aware. On Aug 7 1942 he smashed the second and third fingers of his right hand between a stone and the rear of a truck. He was sent to the office of a doctor who after dressing the injured fingers gave him two intramuscular injections of antitoxin, one in the arm and one in the buttock—from what I understand they were to prevent tetanus. On his way home he began to vomit and have chills. He went to bed the next day his eyes began to swell and he had a generalized urticaria. The chills and later fever continued for three days and the urticaria subsided soon thereafter. He has remained in bed off and on since then. I examined him at his home on September 27 when he complained of generalized muscle pain and weakness, severe pain in the injured hand, occasional dizzy spells, loss of appetite and strength, irritability and nervousness. Objectively he appeared to be weak and apprehensive. There was a generalized muscle tenderness on deep pressure, moderate swelling and thickening of the terminal phalanges of the injured fingers but no evidence of any infection, a fine tremor of the eyelids, tongue and fingers, and increased knee jerks. The blood pressure was 200/100, the pulse rate 64, the heart sounds were distant but regular with a systolic murmur at the apex, the heart was not enlarged and there was generalized arteriosclerosis. The blood Wassermann reaction was negative, blood sugar 73 mg, nonprotein nitrogen 27.9 mg. Present examination reveals that his general condition is about the same as that reported. There is no question in my mind that the hypertension and the arteriosclerosis existed prior to the injury to the right hand and the anaphylactic reaction following the injection of the antitoxin, but here is a man who did laboring work all his life and apparently was in good physical condition who following the occurrences mentioned is today totally disabled. My purpose in sending this information is to ascertain what effects on anaphylactic reaction would have on his preexisting condition. Is there any literature that would aid me in this matter?

P F Cardinale MD Elizabeth N J

ANSWER—It is not entirely certain from the facts at hand whether the patient had an accelerated form of serum sickness or an immediate type of serum reaction due to a previously existing sensitiveness. In either type of reaction a number of complications have been described. It is possible for the anaphylactic type of reaction whether due to serum or to other antigens, to result in various profound responses such as abortion, pronounced gastroenteritis, protracted nervous and toxic states and interference with the normal functions of the liver, kidneys and blood vessels. Serum sickness has been not infrequently reported to cause neurologic complications and particularly neuritis. Among other occasional effects that have been noted as a result of serum sickness may be mentioned edema of the larynx, abdominal pain, gastrointestinal hemorrhage, local purpura, hematuria, jaundice, liver atrophy, optic neuritis, laryn-

geal nerve paralysis, Meniere's syndrome and psychoses. There is no doubt that the patient in question had a preexisting arteriosclerosis and hypertension. This abnormal vascular state may have been the underlying basis favoring the results that followed the serum reaction, but it must be appreciated that it is possible perhaps for similar effects to be produced without any previously existing organic states.

DIAGNOSIS OF TYPE OF ANEMIA

To the Editor—A woman aged 77 has an anemia with 2,438,000 red blood cells and 40 per cent hemoglobin. Neither blood smear nor color index is indicative of pernicious anemia. She has a chronic valvular heart disease with no decompensation, a blood pressure of 100/60 and normal urine. The vaginal examination is negative except for prolapse of the uterus. From the history and examination I was unable to find any place where she could be losing blood except a history of vomiting blood four years ago. Later x-ray examinations of the gastrointestinal tract were negative and she has not lost weight since. What type of iron and liver therapy is indicated? Considering her age and the myocardial damage, is a blood transfusion advisable?
M D Pennsylvania

ANSWER—It would not be possible to say what type of therapy is indicated until the anemia is carefully classified as to morphology and etiology. The mainstay in the differential diagnosis of such an anemia is the laboratory examination. Such determinations as the volume index, saturation index, icterus index, reticulocyte count, platelet count and a careful study of the blood smear should give a clue as to the type of anemia. Further studies such as sternal puncture with examination of the bone marrow, stool examinations and renal function tests, may also be necessary.

The age of the patient and the condition of the heart are not contraindications to giving a blood transfusion. However, if the type of anemia is such that it would respond to specific therapy, transfusions would not be necessary.

COBRA VENOM FOR ANALGESIA

To the Editor—In the *Journal of International College of Surgeons* (3:357 [Aug] 1940) Paul Butler of Orlando, Fla., makes the following assertions as to the remarkable properties of snake venom. He maintains that it has recently been proved that cobra venom has a higher analgesic action than morphine. Believing therefore that the analgesic effect of snake venom and its value in therapeutics cannot alone explain its curative effects and that the evidence indicates a deep effect on the metabolic processes in the human body, I looked through the pages of *New and Nonofficial Remedies* and the only reference to snake venom concerned Lederle's moccasin for hemorrhage (not recommended). Butler appends two references: Burkhardt, Albrecht. Treatment of Rheumatic Disorders with Snake Venom, *Deutsche med Wchenschr* 61:1159 (July 19) 1935, and Spangler R H. Intramuscular Injection of Foreign Protein. Crotalin in 300 Cases of Epilepsy, *New York M J* 107:727 (April 20) 1918. I should like to know if there is any truth in Butler's contention. Has any experimental work been done of sufficient value to entitle it to deserve his encomiums? It seems to me from the paucity of literature that there has not.
Thomas I O'Drain M.D. Philadelphia

ANSWER—The use of cobra venom in clinical therapeutics has been developed in the last eight years by both American and foreign investigators. The most prominent publications from French writers were those of Charles Taguet (*Bull et mem Soc med d hop de Paris* 137:310 [April 29], 651 [Dec 8] 1933) and Albert Calmette and A. Ortoni (*Presse med* 42:112 [Jan 20] 1934).

In this country practically all of the publications have been by Macht and his collaborators (Macht D I. *Proc Nat Acad Sc U S* 22:61 1936; Macht D I, and Spencer Elizabeth C. *J Am Pharm A* 31:146 [May] 1942). The last mentioned is his most recent publication. Other investigators in India and in Argentina have also studied the analgesic effects of cobra venom. According to Macht and his collaborators cobra venom injected in small doses produces analgesia and therefore suitable preparations were first employed for the relief of intractable pain suffered by patients with malignant disease. Macht maintains that he has shown experimentally

that this relief of pain is not due to a peripheral effect on the nerve endings or nerve fibers but to a direct action of the drug on the brain, and the hypothalamus is the center of the cobra venom analgesia.

Cobra venom solution was discussed in a preliminary report of the Council on Pharmacy and Chemistry (*THE JOURNAL*, Oct 5, 1940, p 1196). It was concluded that purified cobra venom is of some value for the relief of pain, especially that of inoperable cancer (its use in the early stages would tend to delay curative measures), that it does not displace morphine completely in more than relatively few cases but it is of value in these few, that it appears to be of limited value in the treatment of trigeminal neuralgia and the various conditions commonly grouped loosely under the names of "rheumatism" and "arthritis", that its therapeutic effects are variable and uncertain in all painful conditions that the disagreeable side actions, including nausea, vomiting, diarrhea and pain of injection—even intense pain at times, mentioned in medical journals—must be brought to the attention of those who use cobra venom, that it must not be recommended for those who are severely ill except those suffering from inoperable malignant tumors or from incurable disease, that the optimum dosage (after the first single dose) remains to be determined, and that the effects are not immediate but may take hours to appear.

CHOREA WITH EMOTIONAL BEHAVIOR DISTURBANCE

To the Editor—Two years ago I saw a girl aged 12 with chorea. After intramuscular magnesium sulfate injections and several hyperthermic treatments she apparently made a recovery and I lost sight of her. Now her mother states that she developed the present symptoms within the past year. She has some purposeless explosive movements, the most distressing of which is a sudden explosive speech outburst during which the patient suddenly uses vulgar or curse words. During conversation she will talk quite intelligently but in the middle of a sentence she will suddenly say "G—d—d—" and then proceed to finish the sentence also while sitting quietly. She will suddenly explode in this manner. The patient does not seem to be psychotic. She lives quietly at home with her grandparents. Her mother works. The patient realizes that this condition is abnormal and expresses a real desire to get well so that she can attend school go to shows and otherwise mingle with others. I shall appreciate any suggestions you may have to offer along the line of treatment. The parents are too poor to afford a special school for the girl.
M D Arkansas

ANSWER—The patient has a recurrence of chorea with emotional behavior disturbances. The latter occurs in a mild way in many cases of chorea. The use of vulgar or curse words in this disease is not rare. The possibility of a degenerative or Huntington's chorea must be thought of, although it is improbable because of her age. The following treatment is suggested. The patient should have absolute rest in bed for six weeks in a darkened room. No visitors and no exciting radio stories or plays should be allowed. One and the same person should act as nurse. The patient should sleep alone in her room. She should eat alone. She should sleep from fourteen to sixteen hours daily. Solution of potassium arsenite in doses of 5 to 7 drops three times daily can be given for thirty days or 5 grains (0.3 Gm.) of acetylsalicylic acid three times daily for twenty days. Lukewarm baths for twenty minutes once daily can also be given for its sedative effect. Insomnia may be treated by bromides or phenobarbital. The heart should be studied to rule out an associated endocarditis.

OVARIAN NEOPLASM

To the Editor—I should like to take exception to the form of treatment as outlined in *Queries and Minor Notes* in the Jan 30 1943 issue under the heading Probable Ovarian Neoplasm. Under the description of the patient's pelvis there is apparently a cervical polyp or other neoplasm partially extruded from the uterus into the cervix. Laparotomy regardless of the associated conditions almost without exception should be postponed until the intrauterine and intra-cervical tumors are removed by the vaginal route. When submucous myomas have been partially or completely extruded through the cervix they are almost always infected and laparotomy carried out in these conditions is hazardous. In this particular case it would appear to me to be advisable to remove the intra-cervical tumor await the closure of the cervix and then perform the necessary abdominal procedure.

WASHING HYPODERMIC NEEDLES TO PREVENT CLOGGING

To the Editor—In doing intradermal tests for allergies there results the problem of washing out each needle so that the test solutions do not become contaminated. I have devised a neat quick way of washing out our needles. The needles are stuck into the lumen of a piece of old duodenal tube. When the tube is clamped shut on one end and a luer syringe applied to the other end alcohol can be swished in and out through the needles thereby cleaning them thoroughly. The needles are then left sticking in the tube as this is an excellent place to keep them until next used.

SULFATHIAZOLE THERAPY OF FIVE HUNDRED PROSTITUTES WITH CHRONIC GONORRHEA

THE CONTROL OF VENEREAL DISEASE
IN WARTIME

HYMAN STRAUSS, M D
AND
ISAAK GRUNSTEIN, M D
BROOKLYN

Medical history shows that there is a great increase of venereal disease during wartime. Prostitutes are a danger to our military and industrial army. Detailed histories of some of our cases reveal twenty to thirty exposures during a twenty-four hour period. In a metropolitan city like New York with huge naval, military and industrial developments, a center for the armed forces on leave or embarkation, this problem assumes such serious significance that it requires immediate and proper attention.

This paper is based on a study of 615 women, culturally positive for the gonococcus, who were hospitalized at the Kingston Avenue Hospital. They had been arrested for actual or attempted prostitution, tried at the Jefferson Market Court and found not guilty or given suspended sentences. However, since they had gonorrhea, the Health Department immediately ordered them hospitalized for treatment as a means of controlling the spread of venereal disease.

Only 20 per cent of these patients, all culturally positive, were noted to have clinical evidence of gonorrhea at the time of the initial examination at our hospital. Repeated examinations revealed a greatly increased percentage of clinically positive cases, owing partly to the discovery and discounting of deceptive methods employed by the patients and partly to the greater accuracy resulting from repeated checkups.

On admission a complete history, including the gynecologic and sociological aspects, was taken, and a general physical examination was done. Then a thorough gynecologic examination, which included the urethra, Skene's and Bartholin's glands, the cervix, corpus and adnexa, was made by both the resident and the visiting staff. Spreads and cultures were taken from the urethra, cervix and, when indicated, from Skene's and Bartholin's glands. Blood for the Wassermann test and the complement fixation test for gonorrhea as well as complete blood counts and urinalyses were performed routinely. When indicated, additional cultures and spreads, sedimentation rates, blood chemical examinations and sulfathiazole determinations were done.

The routine treatment was the administration of sulfathiazole orally in four doses between 6 a m and 10 p m. The patients were ordered to take a minimum of 1,500 cc of fluids daily and to report a diminished urinary output, hematuria or other toxic symptoms. They were advised to avoid direct sunlight. About 20 per cent of these girls received mapharsen concurrently for their syphilis. Urinalyses and blood counts were repeated routinely during the course of treatment. Dosage was not based on body weight.

These 488 patients were divided into three groups among which the duration of treatment and/or the daily dosage varied. Group 1 received 45 grains (3 Gm) daily for ten days, group 2 received 60 grains (4 Gm) daily for ten days and group 3 received 60 grains daily for seven days. Local therapy was not used in this series nor was sulfanilamide. Sulfapyridine, because of its greater toxicity, was used only in some cases when sulfathiazole failed.

The first smear after completion of treatment was taken on the fifth day. At four day intervals thereafter both smears and cultures were taken. At least one smear and culture was taken during or immediately after menstruation. Careful speculum examinations emphasizing the amount, consistency and color of the discharge were made during and after chemotherapy by several members of the staff.

Specimens for culture consisted of swabs taken from the source of the discharge. These were placed in tubes containing 1 to 2 cc of 2 per cent proteose peptone No 3 solution in 0.5 per cent sodium chloride. They were thus transported to the laboratory, where they were inoculated in less than two hours after delivery.

The medium employed was the Difco product recommended by Carpenter. Difco proteose peptone No 3 agar is prepared double strength. Equal quantities of this and a 2 per cent bacteriohemoglobin are mixed under aseptic conditions and plates poured. The swab was removed from the tube and streaked over two thirds of the plate and was rolled from side to side to insure inoculation of all the material. The plate was streaked with a platinum wire at right angles to the original streak to insure dilution and growth of discrete colonies. Approximately 12 per cent of the air was removed and replaced by carbon dioxide. The plates were incubated at 35 C for forty-eight hours in air tight jars. At the end of this time the plates were read first by direct inspection and then with a 1 per cent solution of dimethylparaphenylenediamine monohydrochloride poured over suspected colonies by medicine dropper. If a smear from an oxydase positive colony showed typical gram negative biscuit shaped diplococci and a subculture from such a colony failed to grow on nutrient agar at room temperature, such a culture was considered to be a gonococcus. However, if repeated cultures continued to be positive, further subcultures were made to chocolate agar, plain agar and sugar fermentation mediums (dextrose, maltose and saccharose).

The cultures taken in this laboratory are repeat cultures. The primary cultures were taken by the New York City Health Department.

From the Department of Hospitals City of New York.
From the Department of Gynecology Kingston Avenue Hospital Brooklyn.

The minimum requirements for discharge from Kingston Avenue Hospital were four consecutive negative smears and three cultures. In addition it was required that there should be no gross clinical evidence of the disease (Even all of the foregoing prerequisites in our opinion do not constitute adequate proof of cure because of the relatively brief period of observation.)

When the dosage was raised from 45 grams daily (group 1, total 30 Gm) to 60 grams daily (group 2 total 40 Gm) for ten days the percentage of apparent

Chart 1—Culturally positive 100 per cent

cures was raised by 8.1 and there was no appreciable increase in toxic symptoms. Then the period of treatment was decreased from ten days to seven days with the daily dosage remaining at 60 grains (group 3). The total dosage dropped from 40 Gm to 28 Gm. The 27 per cent increased cure rate, however, has no statistical significance, in our opinion.

In only 2 cases in the entire series did toxic symptoms necessitate interruption of therapy. The first patient had a mild secondary anemia before taking sulfathiazole, i. e. 45 grams daily for ten days. Later since she represented a failure 60 grains of sulfapyridine was given for only three days because she developed a pronounced secondary anemia necessitating a blood transfusion. Without further therapy her cultures became negative and she was discharged. The second patient on the fourth day after taking 240 grams (15 Gm) developed hyperpyrexia, reddened throat, stiff neck, pain and tenderness in the lower part of the abdomen and in the renal areas. She recovered promptly on stopping the sulfathiazole. Symptoms recurred after a repetition of only 60 grains of the drug.

Minor toxic symptoms (i. e. headache, dizziness, slight nausea, faint and transient rashes) were occasionally encountered. However, in none of these cases was it necessary to discontinue treatment.

The vast majority of the patients felt well, had no complaints and usually gained weight. The average net gain in body weight was 2.83 pounds (the maxi-

Chart 2—Six hundred and fifteen patients with positive gonococcus culture. 441 (71.70 per cent) had gonorrhea alone, 173 (28.14 per cent) had gonorrhea and syphilis, and 1 (0.16 per cent) had gonorrhea and lymphopathia venereum.

imum being 21 pounds and the minimum $\frac{1}{4}$ pound). The average period of hospitalization for those with gonorrhea alone was thirty-one days and for those with gonorrhea and syphilis was forty-five days. Most of the patients were between 20 and 30 years of age (the youngest 16 years and the oldest 49 years).

Of the 488 patients having completed treatment and discharged after four consecutive negative smears and three negative cultures, 441 (90.4 per cent) were

negative after the first course of sulfathiazole and 47 (9.6 per cent) were failures after the first course. Of the 47 failures (after the first course) 42 became negative after the second course. [The second course was sulfathiazole in 39 cases. The second course was sulfapyridine in 8 cases, 7 of which were rendered negative immediately. The eighth one required focal therapy in addition and a third course of a sulfonamide compound (sulfathiazole).]

By giving a second course of sulfonamide compounds to the failures on the first course, the number rendered bacteriologically negative was raised from 441 to 483 and the percentage increased from 90.4 to 98.9. Five of the 47 were not bacteriologically negative after the second course. Of the 5 failures after the second course, 3 became negative after the third course of sulfonamides (the first and second courses were sulfathiazole and the third was sulfapyridine). One became negative after cervical cauterization, having failed to respond to two previous courses of sulfathiazole. One failed after a third course (the first course was sulfathiazole, the second sulfapyridine, the third sulfathiazole) but became negative after cervical coagulation.

Bacteriologic analysis of the 47 failures after completion of the first course of sulfathiazole therapy revealed that on the first bacteriologic check-up only 17 cases were positive, on the second check-up 10 more

Chart 3—Six hundred and fifteen patients with positive gonococcus culture.

cases were found positive, on the third check-up 18 additional cases were positive and on the fourth check-up 2 more cases were positive. The first check-up was made five days after completion of therapy and the subsequent ones at four day intervals.

It is obvious, therefore, that one or two negative bacteriologic observations are insufficient to determine cure. Negative evidence here as elsewhere has value only if it is corroborated by repeated identical findings. It follows that increasing the period of surveillance, allowing for more check-ups, diminishes the possibility of overlooking the asymptomatic carrier (latent cases).

The clinical picture may be distorted in some cases because of associated *Trichomonas vaginalis* vaginitis which was present in 67 per cent of our cases on admission and which almost invariably persisted despite the sulfathiazole therapy.

In over 60 per cent of the cases a purulent cervical and urethral discharge which was not caused by *Trichomonas* persisted after completion of sulfathiazole treatment despite repeated negative cultures for the gonococcus. This persistent discharge was presumably due to sulfonamide resistant secondary invaders or to an inflammatory reaction caused by the preceding gonococcal infection. It seems advisable to apply in addition local treatment in order to eradicate this discharge.

If Skene's or Bartholin's glands were affected, discharge (though gonococcus negative) or swelling likewise persisted in many cases after sulfathiazole therapy.

Bartholin's gland abscess was present in approximately 1 per cent of our cases. The incidence of adnexal involvement and postmenstrual flare-ups has diminished definitely since sulfonamide medication has been instituted.

The persistence of a discharge which culturally appears nonspecific throws a heavy responsibility on the clinician when he is asked whether a patient is still infectious. If these patients were observed for a longer period of time, some of those with negative cultures might become positive again. All of us have observed on occasion a reversal of cultural findings after the first or second were negative. Perhaps this is because sulfathiazole is only bacteriostatic, and virulence may be subsequently restored because of failure of biologic response. This phenomenon seems to be partly substantiated by the observation that negative cultures have been found when the smears were simultaneously positive.

Since the immediate success or failure is not always related to the degree of sulfonamide concentration in

Chart 4—Treatment of 488 patients with sulfathiazole

the blood, we may assume that the fluctuations in cultural findings may be caused by immunologic changes producing increased resistance throughout the body or only in the affected mucous membranes or by a diminution in the viability of the gonococcus. Therefore the result of this therapy is either death of all the gonococci (i.e. definite cure) or only attenuation of the organism (i.e. an asymptomatic carrier). In either case the cultures may be found negative. In order to detect this asymptomatic carrier, who is a continuous source of infection, we must try to improve our diagnostic methods (cultural technic, culture mediums, provocatives and so on).

This resolves itself into the problem as to when these patients are no longer infectious. We must consider, first, clinical, bacteriologic and symptomatic cure for the patient's own sake, second, noninfectivity to others as a public health concern.

It has been well established that a known positive untreated case may yield negative cultures and since we have no one test such as animal inoculation which definitely marks the time of clinical cure, we are left with but one alternative—we must use repeated cultures,

smears and clinical observations over a sufficient period of time before passing final judgment. The almost incredible percentage of apparent cures should not cause us to relax our vigilance. We have found positive cultures, smears and/or clinical evidence after three negatives. We have also found little or no tox-

icity in this large series of patients who are otherwise healthy except for this usually local pathologic condition. Because of these two factors one should not hesitate to treat even doubtful cases.

In our opinion at least four consecutive negative cultures and smears should be made at weekly intervals and the patient should be clinically negative and be under a further period of observation of at least six weeks before she can be reasonably regarded as non-infectious. Additional studies will prove whether it is safe to decrease the dosage, treatment time and the period of observation. The ultimate desideratum of cure in female gonorrhea will be the failure to reproduce the infection after human exposure.

With respect to the 109 infected patients discharged by the Department of Health by special releases before treatment was completed the following is evident:

Assuming that only 100 of these 109 girls return to prostitution as a livelihood, and allowing them sixty-five days for idleness and menses, and granting the average number of daily exposures to be even less than

TABLE 2—Treatment with Sulfathiazole

their admitted minimum of twenty, approximately half a million men could be infected in a year while the girls are under private medical care and yet continue to practice their profession at the same time. The futility of follow-up in ambulant patients whose very livelihood depends on deliberate and persistent reexposure is obvious. When, in addition, the asymptomatic carrier is considered, the problem is complicated many fold.

It is clear, therefore, that prostitution by its very nature requires adequate hospitalization if there is to be not only proper treatment but also control of the spread of infection. Repeated offenders endangering the nation's health in wartime should be interned for the duration and educated to do useful work for the war effort. Above all this may lead to their permanent rehabilitation. Equally obvious is the fact that the added cost of such hospitalization and rehabilitation will be more than offset by considerations of health and the undoubted prevention of loss of time and efficiency in our war industries and armed forces on whom our national safety depends.

SUMMARY AND CONCLUSIONS

A study of 615 hospitalized gonorrheal patients shows that 60 grams of sulfathiazole daily for one week gives a 95 per cent apparent cure rate. The administration of sulfathiazole or sulfapyridine to the failures increases this rate to 98.9 per cent.

This very high cure rate must, however, be carefully scrutinized in order to determine the permanence of our immediate results. It must be ascertained in each case whether there has been sufficient treatment and an adequate period of observation.

Furthermore, and most important, it must be determined whether the criteria of cure employed are sufficient to insure protection of the public against further infection. The difficulty in detecting the asymptomatic carrier cannot be emphasized too strongly. Health departments defeat their own purpose by hospitalizing patients to control infection and then releasing them before cure in the custody of a private physician because of an interpretation based on the present law.

We feel that a prostitute, although treated, remains potentially infectious for approximately three months, during which time, if at large, she is a source of infection and as such forfeits her right to the benefit of doubt.

The cure of an infected prostitute requires adequate compulsory hospitalization. Repeated offenders should be interned for the duration and compelled to aid in the war effort. If the law now does not adequately remove this public health hazard as it does in most contagion, remedial statutes should at once be enacted toward that end.

If the state can call on a man for his life in this grave emergency, surely the common welfare demands that the "right" of an infected prostitute to be at liberty while still infectious be disallowed, at least for the duration of the war.¹

¹ Dr. E. A. Horowitz granted the use of those patients who were in his service. Dr. Julius Sass, pathologist, and Miss Lillian Robbins, bacteriologist, rendered assistance.

Choice of Words—It is customary to describe one whose powers of expression are above the average as having a good 'choice of words'. This goes to the heart of the matter. Choice means careful selection and requires thought. The doctor who expresses himself with clarity and precision thinks before he speaks. He has established a lifelong habit which gives him speed in choosing the right word for any shade of meaning. Many have not acquired this habit and rely on the stereotyped solecisms of a strictly limited medical jargon, which comes so easily to the tongue. Too often these unworthy phrases find their way into print. No doubt the pendulum will swing again and the profession demand a higher standard of literary expression than at present prevails.—The Decay of Medical Language, editorial, *New Zealand M. J.* 41:237 (Dec.) 1942.

TOXIC REACTIONS FOLLOWING THERAPY WITH SULFAPYRIDINE, SULFATHIAZOLE AND SULFADIAZINE

HARRY F. DOWLING, M.D.
AND
MARK H. LEPPER, M.D.
WASHINGTON, D. C.

The value of the sulfonamide drugs in the treatment of many infectious diseases is evidenced by their widespread use. As these drugs have been employed more frequently, physicians have become increasingly aware that certain toxic effects may follow their administration. A variety of toxic reactions have been described in the literature, all of which rightly serve to make physicians conscious of the hazards to be encountered when these compounds are given to patients. And yet, reports of individual instances or of groups of cases in which a complication occurred following the use of one of the sulfonamides will not serve to show the relative frequency of these complications or their severity and importance. These can best be portrayed from a study of a large group of patients treated and observed under uniform conditions. The present paper is an analysis of the toxic reactions encountered in all the patients treated with sulfapyridine, sulfathiazole or sulfadiazine whose treatment was personally observed by one or both of us up to Jan. 1, 1943 either at the Gallinger Municipal Hospital¹ or in private practice. Most of these patients were treated for pneumonia, but a great many were given sulfonamides for other infectious diseases such as meningitis, endocarditis, gonococcal arthritis and pyelitis. A few of the patients were ambulatory. All patients had complete blood counts and urinalyses before the sulfonamides were started and frequently usually every alternate day, thereafter as long as the drugs were being given. Determinations of the free blood sulfonamide level were done on hospital patients usually daily during the course of therapy. On a few of the patients determinations of free and combined sulfonamides were made. Hospital patients were observed and questioned daily for the presence of toxic reactions, and ambulatory patients three times a week.

Table 1 shows the incidence of toxic reactions for each of the three sulfonamide drugs used. When two or more courses of a sulfonamide were given, only the first course is included in the table. It will be seen that the toxicity from sulfadiazine was less than that following sulfathiazole, which in turn was less than that obtained with the use of sulfapyridine. Among 498 patients treated with sulfapyridine, toxic reactions occurred in 149, or 29.9 per cent. Fifty-eight, or 11.8 per cent, of the 321 patients receiving sulfathiazole suffered from toxic effects while among the 660 patients to whom sulfadiazine was administered only 51, or 7.7 per cent, experienced toxic symptoms. These differences were found to be significant when tested by the chi square method. The greatest difference

Miss Ruth Mayer rendered technical assistance and Miss Louise Mauser assisted in the tabulations.

Dr. Lewis K. Sweet cooperated in the treatment of the patients from the Infectious Disease Service who are included in this report.

From the George Washington Medical Division, Gallinger Municipal Hospital, and the Department of Medicine, George Washington University School of Medicine.

¹ Several of our former colleagues have cooperated in this work at different times including Drs. T. J. Abernethy, Harry A. Feldman, Clarence R. Hartman, Frank A. Jenkins and Samuel J. Sugar.

² The sulfadiazine and sodium sulfadiazine used in this study were furnished by the Lederle Laboratories, Inc.

in the toxic effects of the three drugs was to be found in the incidence of vomiting, which was present in 20.5 per cent of the patients treated with sulfapyridine, in 5.9 per cent of those receiving sulfathiazole and in 1.4 per cent of the patients given sulfadiazine. These differences are statistically significant. The frequency of vomiting in our series was less for all three drugs than that found by other investigators. This is probably due to the high proportion of Negro to white patients in our series (more than 2 to 1). An analysis of our patients treated with sulfapyridine showed that vomiting occurred in 37.6 per cent of the white patients and in only 2.2 per cent of the Negroes receiving this drug. It is our experience that the same relationship holds for the other sulfonamides also.

The presence of a renal calculus was diagnosed when gross hematuria, anuria or pronounced unexplained oliguria, pain over the kidneys or ureters or any combination of these was encountered. Neither the presence of sulfonamide crystals in the urine nor microscopic hematuria was considered indicative of the presence of a calculus, since these elements are present in the urine of a great many patients receiving the sulfonamide drugs under consideration. Using the criteria that have been named for diagnosis, we found kidney stones in 1.6 per cent of the patients receiving sulfapyridine, 2.8 per cent of those receiving sulfathiazole and 1.5 per cent of those receiving sulfadiazine. These cases will be discussed later in more detail.

We have placed in one group all the patients with fever, dermatitis and conjunctivitis (or episcleritis) resulting from the use of the sulfonamides, since these complications often occur simultaneously and since all three phenomena are apparently due to a similar type of sensitivity to these drugs. The incidence of these reactions following sulfapyridine and sulfadiazine was relatively low, 2.4 and 2.0 per cent respectively, as compared with 6.2 per cent in the patients receiving sulfathiazole. These differences are significant by the chi square test when the reactions following sulfathiazole are compared with those following sulfapyridine or sulfadiazine but not in the case of sulfapyridine as compared with sulfadiazine.

In the presence of a severe infectious disease, disorientation and mental confusion resulting from the use of drugs is difficult to evaluate. Nevertheless, after studying this symptom carefully in its time relationship to sulfonamide administration we are reasonably certain that these drugs contributed to the presence of mental confusion in 2.4 per cent of the patients receiving sulfapyridine, in 1.6 per cent of those given sulfathiazole and in 1.5 per cent of those to whom sulfadiazine was administered. These differences are not statistically significant.

The incidence of hematologic complications was not especially different for any of the three drugs except for the occurrence of 7 cases (1.4 per cent) of acute hemolytic anemia following sulfapyridine and only 1 each following sulfathiazole and sulfadiazine (0.3 and 0.2 per cent respectively). Leukopenia with a drop in the white blood cells below 4,000 per cubic millimeter was observed in 6 patients (1.2 per cent) receiving sulfapyridine, in 4 (1.2 per cent) receiving sulfathiazole and in 6 (0.9 per cent) receiving sulfadiazine. Granulopenia in addition to the neutropenia occurred in 4 of these sulfapyridine treated patients, in 2 of the sulfathiazole treated patients and in 3 of the sulfadiazine treated patients. The only difference which is sig-

nificant in the aforementioned group is the higher incidence of acute hemolytic anemia following sulfapyridine as compared with that following the other two drugs.

A definite leukocytosis, independent of the disease for which treatment was being given, developed in 2 patients to whom sulfadiazine was administered. There were increases in the leukocyte counts to 57,000 and 63,700 respectively and an increase in the mature polymorphonuclears and band forms. These counts returned to normal within three days after the cessation of sulfadiazine therapy.

Less frequent toxic complications were yellow vision in 1 patient who received sulfathiazole and 1 who received sulfadiazine and peripheral neuritis in 1 patient who was given sulfapyridine. This case has been reported elsewhere by Sugar.³

RENAL CALCULI

The symptoms which led to the diagnosis of sulfonamide calculus in our patients were pain over kidneys and/or ureters in 7 cases, gross hematuria in 6 gross

hematuria and kidney pain in 4, anuria or definite oliguria in 3, anuria and kidney pain in 3 and oliguria and gross hematuria in 2. The condition of 1 other patient was not diagnosed during life. This patient showed nothing suggestive of a calculus except nitrogen retention and microscopic hematuria but after death from endocarditis she was found to have a sulfadiazine calculus in the pelvis of one kidney. The only other death in this group was of a patient with a pneumococcal pneumonia who died following the formation of a sulfathiazole calculus. The death of each patient was attributable to the original disease and not to the kidney stone.

The symptoms of calculus formation began anywhere from the first to the tenth day of treatment. Every patient who developed calculi had received doses of the drug of 1 Gm. or more every four hours, sometimes supplemented by the sodium salt intravenously, and every patient was either dehydrated before treatment began or received insufficient fluids in proportion to the dose of the drug given. Calculi were particularly likely to occur in patients who were being treated for

3 Sugar, S. J. Peripheral Neuritis Following the Administration of a Glucose Sulfapyridine Compound. *New England J. Med.* 226: 1021-1022 (June 25) 1942.

meningitis or endocarditis, because these patients were often given large amounts of the drugs so that high blood levels might be maintained. Among the 82 patients receiving sulfadiazine for meningitis or endocarditis, 5 (6.1 per cent) developed renal calculi, while among the remaining 578 patients who were given sulfadiazine for other illnesses the 5 patients who developed calculi represented only 0.9 per cent of all the patients treated. Nine patients with meningitis or endocarditis were given sulfapyridine and 1 (11.1 per cent) developed a calculus. Among the remaining 499 patients who received sulfapyridine 7, or 1.4 per cent developed calculi. Only 4 patients received sulfathiazole for the treatment of endocarditis or meningitis. None of these developed calculi. Among the 317 patients receiving this drug for other diseases 9 or 2.8 per cent, developed calculi.

When all the patients developing calculi are considered, with the exception of those treated for meningitis and endocarditis, the difference between the sulfadiazine and sulfathiazole treated groups is the only one which is significant.

excessively or is already dehydrated at the start of treatment the urinary output may become too small to keep the crystals in solution.

Brown, Thornton and Wilson⁴ showed that the higher the level of sulfapyridine in the blood the greater was the possibility of calculi being formed. From table 2 it will be seen that this same relationship holds in our patients treated with sulfapyridine, sulfathiazole and sulfadiazine. Among 117 patients whose maximum free blood sulfonamide levels were between 1 and 3.9 mg per hundred cubic centimeters none developed renal calculi. In the groups of patients whose highest free sulfonamide levels were 4 to 6.9 or 7 to 9.9 mg per hundred cubic centimeters there were 1.1 and 1.3 per cent of the patients respectively who developed renal calculi. Among the 290 patients whose highest free blood sulfonamide level was 10 mg or more per hundred cubic centimeters 10 or 3.4 per cent, developed calculi. It is also interesting that whereas 3 patients whose free blood sulfapyridine levels were between 4 and 6.9 mg per hundred cubic centimeters developed calculi no patients with these maximum levels following

TABLE 2—Incidence of Renal Calculi in Patients Treated with Sulfonamides According to the Highest Blood Level Attained

The treatment given 20 of the 26 patients with calculi was merely the discontinuance of the offending sulfonamide and the forcing of fluids. Three patients who had been treated with sulfathiazole and the 1 who had been given sulfadiazine required cystoscopy with catheterization and lavage of the ureters. One of these patients with a sulfathiazole calculus required this procedure twice. It was effectual in starting the urinary flow in all cases. The disease of 1 patient with renal colic during the treatment of meningococcic meningitis with sulfadiazine was considered more serious than the complication, and the drug was continued while fluids were given at the rate of 5000 cc a day. The pain disappeared and no further symptoms occurred during the remainder of the sulfadiazine therapy. As stated before, 1 patient died in whom the calculus was not diagnosed and who consequently received no treatment for it.

The formation of renal calculi is a serious and sometimes lethal complication of sulfonamide therapy. The mechanism is the crystallization of the sulfonamide or its acetyl derivative in the pelvis of the kidneys, ureters or collecting tubules. The urinary flow is diminished or stops completely, nitrogen retention develops and death may ensue unless the obstruction is removed. If fluid intake and consequently fluid output through the kidneys is sufficient to keep these crystals in solution calculi will not form. If the fluid intake is insufficient or if the patient is vomiting, has diarrhea, is sweating

sulfathiazole or sulfadiazine therapy developed calculi. In the sulfathiazole treated group no patients developed calculi unless their maximum free blood sulfathiazole levels were 7 mg or more per hundred cubic centimeters. In the sulfadiazine treated group none developed unless the corresponding blood sulfadiazine levels were 9.2 or more.

It is apparent that when the intake and consequently the blood levels and urinary output, of the sulfonamides are kept low, renal calculi occur rarely if at all. This is borne out by the fact that, among the 182 patients whom we have treated with sulfadiazine in doses of 0.5 Gm or less every four hours there has not been a single instance of renal calculus formation. The same is true for the 43 patients receiving sulfathiazole in similar low doses.

Our observations indicate that sulfadiazine administered in these low doses is as effective against pneumococcic pneumonia as when 6 Gm a day is given. We have now treated 123 patients with pneumococcic pneumonia in this way with eleven deaths, or a 9 per cent case fatality rate. This compares favorably with our results and those of others in the treatment of pneumococcic pneumonia with higher doses of sulfapyridine.

diazine⁶ If further observations confirm our findings, the administration of these smaller doses should be the optimal way to treat patients with pneumococcic pneumonia

The other method of preventing renal calculi following sulfone treatment is to give sufficiently large amounts of fluids to insure an adequate renal output no matter how high the dosages of the drug In every case in which a sulfonamide calculus occurred among our patients, the patient was dehydrated or took insufficient fluids after therapy began, or a large intravenous dose of the sulfonamide had been given without sufficient fluids to take care of adequate renal output We recommend a total of 3,000 cc of fluids a day for patients receiving the sulfonamides, or enough fluid to insure a urinary output of at least 1,200 cc a day We have been able in several instances to give sufficient sulfadiazine to keep the free blood sulfadiazine level constantly at 20 mg per hundred cubic centimeters or above, without evidence of renal calculus formation, by giving large amounts of fluids at the same time The proper relationship between fluids and sulfonamide intake is the key to the prevention of calculi

DERMATITIS, CONJUNCTIVITIS AND DRUG FEVER

In table 3 are shown the cases of dermatitis, conjunctivitis and/or drug fever encountered by us Since reactions following second and successive courses of the sulfonamides are included in this table, the totals are greater than those in table 1, which includes only the first courses of the three sulfonamides Sulfathiazole was responsible for a larger number of these reactions than either of the other drugs, and the reactions were more varied in type when they followed sulfathiazole While sulfapyridine caused only maculopapular rashes and sulfadiazine both maculopapular and erythematous (scarlatiniform) types, sulfathiazole therapy was followed by 3 erythematous, 4 maculopapular, 7 nodular, 1 urticarial and 1 petechial rash In patients receiving the first course of a sulfonamide, the onset of the rash occurred between the second and sixteenth day of treatment with the drug, nearly two thirds occurring between the sixth and tenth days In the patients developing rash or fever following the second course of sulfathiazole, the reaction in 1 patient began on the third day of the second course, in other patients on the fourth, fifth and seventh days, while 1 patient developed a rash with itching two hours after the first dose of the second course was taken

Leukocyte counts during the height of the rash, drug fever or conjunctivitis ranged from those within normal limits to one which reached 64,700 per cubic millimeter, the majority being below 14,000, however In the cases of conjunctivitis without dermatitis there was no leukocytosis unless drug fever was also present In no instance was there an eosinophilia

In every case the rash and fever subsided within four days after the cessation of sulfone therapy The fact that no cases of exfoliative dermatitis occurred may be

attributed, for the most part at least, to the fact that sulfonamide therapy was stopped promptly as soon as the rash appeared

HEMATOLOGIC COMPLICATIONS

In all of the cases of leukopenia which developed, the leukocytes remained above 3,000 per cubic millimeter except in 1 patient, in whom they reached 2,340 per cubic millimeter at the lowest level The onset of leukopenia occurred anywhere from the third to the sixteenth day of sulfonamide treatment There was no case of agranulocytosis in the series, a fact which may have been due to prompt detection of the abnormality in its milder stages and immediate discontinuance of the sulfonamide In many instances the leukocyte count was again within normal limits on the day following discontinuance of sulfonamide therapy, although in the majority of cases a longer interval was required, the longest being six days

An acute hemolytic anemia with a drop of 1 million or more red blood cells, occurred in 7 patients receiving sulfapyridine and in 1 each receiving sulfathiazole and

sulfadiazine These anemias began on the second to the seventh day following the commencement of treatment Sulfonamide therapy was discontinued promptly in every case, but the erythrocyte counts remained low and in some cases continued their downward courses In 1 patient the red blood cells reached 1,700,000 per cubic millimeter with a hemoglobin of 34 per cent and the patient died, presumably as a result of his pneumonia and the added burden of the anemia In most instances transfusions were employed to bring the red blood cells up to normal levels, although they usually rose slowly without this assistance

AGE AND SEX DISTRIBUTION OF TOXIC REACTIONS

We have computed the relative number of toxic reactions occurring in males as compared with females There was no significant difference in the percentage of any of the toxic effects in the two sexes with the exception of vomiting This occurred more than twice as frequently in females as in males, regardless of the drug used It was present in 15 per cent of the male patients receiving sulfapyridine and in 33.5 per cent of the females The corresponding figures for sulfathiazole were 5.2 and 11.3 per cent and for sulfadiazine 1.2 and 3.1 per cent

There was no apparent difference in the number of toxic reactions in the various age groups, although

the lowest age group was poorly represented, there being only 33 patients under 10 years of age in the entire study

COMMENT

Although the sulfonamides have been used extensively for several years and nearly every physician has had some experience with them, nevertheless there is no common agreement as to the seriousness of their toxic effects. It is the common practice of many physicians to use them in a great variety of diseases, even when the indications for their use are not specific (or, indeed, very clear), since these drugs have, as they say, practically no toxic effects. On the other hand many physicians particularly those who have seen fatalities attributable to these drugs, believe that they may cause serious or fatal complications even under the most careful regulation of treatment and observation of the patient. We believe that the figures which we have presented do not support either of these extreme views. We have shown that toxic reactions occur following the use of sulfapyridine, sulfathiazole and sulfadiazine in descending order of frequency, but that the serious complications are few in number when the patients are watched closely, when the drugs are stopped promptly if reactions occur, and especially when sulfadiazine is used. Only 3 patients in the entire group died at a time when a complication of sulfonamide therapy was present. In 2 of these who had renal calculi the deaths were unquestionably due to the diseases for which the sulfonamides were being given. In the third patient, who developed acute hemolytic anemia in the course of sulfapyridine therapy for pneumonia death may have been contributed to by the drug reaction. Thus it is seen that 1564 courses (including second and later courses) of the sulfonamides were administered to a large group of patients for the most part under the conditions which exist in a city hospital with a minimum of serious toxic reactions and only one fatality which might have been due in part to the sulfonamide administered.

The question of how best to avoid toxic reactions is best answered in two parts. First, renal calculi may be avoided by the use of sulfadiazine in preference to sulfathiazole and sulfapyridine, and by preserving the proper balance between the amounts of drug and fluids given. When good results can be expected from the treatment of a disease with relatively small doses of a sulfonamide, as we have shown to be the case with sulfadiazine in pneumococcal pneumonia, this method of avoiding renal calculi should be taken. When larger doses are needed they can be used without the formation of calculi if careful attention is paid to fluid intake and output.

Secondly, with regard to other complications, vomiting is almost completely absent when sulfadiazine is used, while the chances of producing drug fever, dermatitis, anemia and leukopenia following sulfadiazine therapy are either the same as or less than if other sulfonamides are used. Even with sulfadiazine a few toxic reactions of this sort will nevertheless occur. Serious and fatal results can be almost completely prevented by having blood counts taken every other day and by careful examination of the patient every day and by discontinuing the drug promptly if toxic reactions appear. We believe that in the light of present knowledge only by the use of the measures outlined can sulfonamides be given with the maximum of safety to allow them to be properly used in all cases where they are needed to achieve their full therapeutic effects.

SUMMARY AND CONCLUSIONS

1 Sulfapyridine was administered to 498 patients with toxic effects in 29.9 per cent, sulfathiazole to 321 patients with toxic effects in 11.8 per cent and sulfadiazine in 660 patients followed by toxic reactions in 7.7 per cent. Detailed analysis was made of the toxic reactions encountered in the use of each of these drugs.

2 Renal calculi were found least frequently in patients treated with sulfadiazine or sulfapyridine. Their frequency varied in direct proportion to the maximum level of free sulfonamide in the patient's blood. None occurred in patients given 0.5 Gm of sulfadiazine or sulfathiazole every four hours or less. When larger doses of these drugs were given renal calculi occurred when fluid output was diminished for some reason.

3 Blood dyscrasias occurred less frequently following sulfadiazine and sulfathiazole. The only death in the entire series which might be partly attributable to sulfonamide therapy occurred in a patient with acute hemolytic anemia following sulfapyridine therapy.

4 The optimal therapy for most infectious diseases at the present time involves the use of sulfadiazine, in low doses whenever possible but in high doses when necessary, provided there is careful regulation of fluid intake and output and frequent blood counts and urinalyses, combined with close observation of the patient.

THROMBOCYTE DEFICIT

THE BEHAVIOR OF THE BLOOD PLATELETS IN DILATION OF VASCULAR STASIS OF THE EXTREMITIES

MILTON L. R. MAYNARD, MD
WITH THE COLLABORATION OF
NEIL HOLLINGER, AB
SAN JOSE, CALIF.

This report is rather incomplete in its data and conclusions because the two years in which I have been collecting cases have not permitted the detailed anatomic and physiologic searchings that seem indicated. However, I feel that in these days of marching feet any research that will contribute to our knowledge of the circulation of the lower extremities is worth while. The basis of this study has been a comparison of the platelet counts on blood taken from the ear of patients with circulatory diseases of the legs with counts on blood taken immediately from the right and the left foot.

If the circulation of blood is sufficiently slowed or otherwise becomes incompetent in an extremity and thereby reduces the nutrition of an area to a point of tissue damage, certain phenomena will occur. These phenomena are dependent on failure of oxygen supply and failure of removal of carbon dioxide and catabolic products. The result is a disturbance of normal cell function, accumulation of fluid and of serum proteins, inflammation and finally tissue death. Within these areas the blood vessels suffer as a part of the processes of decompensation. The vaso vasorum fail to keep up a healthy state of nutrition, and vascular tone is lost. With this loss of tone dilatation occurs, and the blood flow is further slowed. As the blood in the large veins becomes further charged with carbon dioxide and waste products damage to the intima appears.

Read before the Section on Dermatology and Syphilology at the Ninety-Third Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1942.

With this slowing of the blood flow the thrombocytes drop from the axial stream and adhere to areas of intimal damage, and white thrombi form. Partial thrombocyte disintegration occurs in these thrombi, and the products of the dissolution enter the blood stream in increasing concentration.

If one accepts the observations of Ceder, Zon and Crigler,¹ who demonstrated rather competently that thrombocytes are the main and probably the sole vehicles for histamine in the circulating blood, one can recognize the role that this potent substance must play in the development of the sensitization of the skin.

This is the picture of circulatory stasis disease of the lower extremities the result of which is edema, dermatitis and ulceration—also pigmentation and hemorrhage and accumulation of serum protein in extravascular areas. The dermatitis may not be confined to the area of stasis alone but, owing to the catabolites acquired through disturbed nutrition and cellular disintegration may develop on other areas of the body, most usually on those areas exposed to light. The solar sensitivity of the patient with varicose dermatitis is well known. The other products of disturbed cellular metabolism with changes in hydrogen ion concentration are likewise to be considered a source of trouble but are not investigated in the development of this paper.

The accidental observation that thrombocytes were definitely diminished within the capillaries of the feet of persons who suffered from chronic stasis diseases of the leg and of those with lichen chronicus simplex of the same areas led to a procedure which I have designated the "thrombocyte deficit" test. The results of this test in more than 200 cases have helped me to construct a picture of the degree of damage suffered by an extremity from such stasis and occasionally predict its chances of repair. This has been useful in the clinical management of cases presenting involvement of the leg. I reported a smaller series of cases before the dermatologic section of the California Medical Association in May 1940. This paper was not published and has been developed to include the larger studies in the present paper.

Something should be said regarding the origins and behavior of blood platelets that are definite problems in an investigation of this type.

1 Platelets may be formed from the breaking up of megakaryocytes but may be caused to clump together again only to break apart a second time and reform as individuals within the course of a few minutes. This suggests that the platelets in the cases considered are not undergoing dissolution, however, the reduction of the ear count considerably below normal in long standing cases indicates an actual loss of the platelet itself.

2 Platelets may fragment into smaller forms while passing through capillaries. This presumably gives an apparent increase in count in some circumstances, a skilful technician will avoid this pitfall, however.

3 Agglutination of platelets may be precipitated by a slight modification of plasmatic equilibrium. Agglutination is lessened by experimental asphyxia and in anaphylactoid purpura. We would therefore expect a lessened agglutination in these affected legs, for asphyxia is certainly present.

4 The distribution of platelets in the vessels of different organs varies widely. There are variations in parts of the circulation or even in the same vessel at the same

time. Showers of platelets appear, only to be followed by an extreme scarcity within a short interval. Vasomotor changes, stagnation or agglutination occurs frequently. Tocantins² found that the number of platelets in arterial blood of the upper extremity was significantly higher than in venous or cutaneous blood. This was not true of the erythrocytes. The taking of the several counts should therefore be done within a short time of

each other. The consistency of the findings by repetition in the same case indicates that a reasonable constancy of count can be expected.

5 Seasonal variation, time of day, activity, menstruation, digestion, age, race, posture, temperature, altitude, pregnancy and various diseases may be lumped together as other factors of definite influence on the counts.

It is our object in this paper to present as a preliminary report a method of comparison of platelet

Although variations of platelet counts in extremities relative to postural changes are discussed by Tocantins,³ a search of the literature has not disclosed any similar investigation. Other studies and reports of changes in the circulatory blood in areas presenting cutaneous disease have been made and reported by Kovacs,⁴ Piscane,⁵ Helmrich,⁶ Ratschow,⁷ David,⁸ and Knott and Pearson.⁹

Kovacs compared the local blood picture in the presence of different cutaneous diseases with finger blood in 50 cases. He investigated the changes in the blood cell counts in the location of the disease. The neutrophils, eosinophils, basophils, monocytes and lymphocytes were studied in 6 cases of psoriasis, 5 cases of erythema induratum, 6 cases of erythema multiforme, 6 cases of urticaria, 3 cases of prurigo, 2 cases of pityriasis rosea, 5 cases of chronic eczema, 2 cases of lichen ruber planus, 4 cases of dermatitis herpetiformis, 4 cases of dermatitis artificialis, 2 cases of arsenphenamine dermatitis and 1 case each of neurodermatitis, erythema elevatum diutinum, mycosis fungoides and parapsoriasis.

Analysis of this study shows that in only the chronic type of lesion was there any variation in the blood cell counts. Evanescent or noninfiltrative diseases such as urticaria and pityriasis rosea showed no change in cellular types. The cases are too few in number for practical interpretation.

Piscane found that the venous pressure was elevated in all forms of varicosities. Capillary pressure was normal.

Helmrich directed attention to the blood picture in the pathologic cutaneous area "in loco" by examining the blood in the papule of a tuberculin reaction and found an increase in the lymphocytes.

Ratschow examined the blood flow in diseased extremities by means of roentgen rays.

David compared blood taken from the finger tip, as did Kovacs, with the blood of a pathologic cutaneous area and concluded that, as would be expected, there was a fixed deviation in the proportion of the local blood

structure and the foreign (finger tip) picture. The search was not sufficiently followed to develop a method for differential diagnosis.

Knott and Pearson found increases in eosinophils following the injection of histamine or proteins in sensitized persons.

These studies which compare finger tip blood with lesion blood show that such blood cell changes are found, as might be expected, in lesions that show similar alterations in a biopsy, they do not give an index of changes dependent on blood velocity and nutritional damage. I believe that it will readily be seen that the studies are not comparable. Furthermore, reference to the thrombocytes has not been found in these reports.

A series of 20 cases is presented for the purpose of illustration in table 1, and a summary of 61 cases collected in 1939 is given in table 2. Table 3 shows the distribution of the counts according to the clinical results and table 4 the distribution of the pathologic condition in relation to the counts.

In 2 cases finger counts were done in addition to the others. The finger blood corresponded to the ear count in these cases, so that I did not continue the practice. This is further borne out by numerous relatively normal counts on blood taken from the leg of persons not exhibiting any apparent vascular anomaly. Bleeding times were also studied for a while, but when it was found that they gave no significant information they were stopped.

Counts of the white and red corpuscles were also done with a few of the platelet counts, but the variation in

TABLE 3—Clinical Correlation of Counts

these cells was in no wise proportionate to the platelet count. The variations were largely within a normal margin of error.

The venous blood of the dorsalis pedis vein has shown a platelet count comparable to although consistently lower than the ear count. This would seem to indicate that the sharp reduction of platelets in the smaller capillary areas is secondary to the development of a congestive sclerosis. The number of platelets in the

Complete investigation of the heart, including an electrocardiogram, was negative. She was given numerous diathermy treatments to the neck, shoulder and arm with little relief.

Examination—Three weeks after the onset of symptoms, the patient was in severe pain. The neck was held toward the left and the left arm was supported by the right. Any movement of the neck to the right or traction on the left arm accentuated the pain. There was considerable muscle spasm in the neck and in the left shoulder girdle. There was exquisite tenderness over the brachial plexus posterior to the scalenus anticus muscle as well as over the scalenus anticus itself. The left index finger was almost completely anesthetic, anteriorly and posteriorly, and sensation was reduced in the middle finger. The index finger could be moved only with the greatest difficulty. Complete flexion of this finger could not be carried out. There was no other weakness of the arm or hand and no disturbance of the reflexes could be made out.

X-ray examination of the cervical spine was negative except for loss of the cervical lordosis.

Spinal fluid examination showed normal dynamics, cell count and protein and the Wassermann reaction was negative.

Diagnosis—A rupture of one of the lower cervical intervertebral disks was suspected at the time but it was felt that the pain in the heart could not be explained on this basis.

Course—Procaine injection of the scalenus anticus muscle, the cervical plexus and the first five thoracic sympathetic ganglions failed to relieve the pain. Diathermy, massage and large quantities of opiates were continued for several weeks after which time the pain began to abate. Since then there has been gradual improvement in her symptoms, until in the last six months she has been relatively free of pain, however, when she becomes tired after considerable activity the old pain recurs for a short time.

Examination on Sept 29, 1941 failed to reveal any muscle spasm in the neck or shoulder. Pressure over the seventh cervical nerve root however, still reproduced the pain. There was no weakness in the arm, all reflexes were normal and the sensation in the index and middle fingers had returned to normal. The patient now continues her occupation as a church organist without difficulty.

COMMENT

Descriptions of this syndrome have appeared in the literature from time to time during the last few years, but no one to our knowledge has proved before that it could be due to a rupture of one of the lower cervical intervertebral disks. Nachlas¹⁴ in 1934 described a syndrome of pseudoangina pectoris originating from demonstrable hypertrophic changes in the cervical spine. He felt that the irritation and compression of the cervical nerve root, secondary to these arthritic changes, were the cause of the radiating pain. Hanflig¹⁵ in 1936 described a group of 30 cases presenting pain in the shoulder girdle, arm and precordium due to hypertrophic arthritis of the lower cervical spine. He thought that these cases were frequent and representative of a large group of persons with symptoms commonly classed as neuritis. Reid¹⁶ in 1938 stated that pressure on the brachial plexus by a cervical rib and scalenus anticus muscle could cause pain simulating angina pectoris or coronary thrombosis. Numerous authors have reported cases somewhat similar to ours due to the scalenus anticus syndrome.¹⁷

Finally, in a series of papers which were published between 1936 and 1940, Turner and Oppenheimer¹⁸ reported a series of 50 cases presenting symptoms quite like those reported by us. They believed that the arthritis which was found in the cervical spines of their patients was the result of thinning of the intervertebral disks and actually played no part in the production of symptoms. They cited the works of Keyes and Compere,¹⁹ who showed that destruction of or injury to the intervertebral disk could produce hypertrophic arthritis. Turner and Oppenheimer believed that narrowing of the intervertebral foramina, which resulted from thinning of the intervertebral disk, caused the nerve root pressure. They called this condition discogenetic disease.

As a result of our experience with a large group of ruptured intervertebral disks in the lower lumbar region, we, like Turner and Oppenheimer, have come to believe that hypertrophic arthritis rarely causes nerve root pain. We are also in complete agreement with Keyes and Compere, having watched spur formation develop along the edges of vertebrae adjacent to a ruptured disk in several cases. We do not agree, however, that narrowing of the intervertebral foramina, which results from thinning of the intervertebral disks, often produces nerve root pressure. Such narrowing can occur only in the vertical diameter. Study of the foramina of the cervical spine is sufficient to convince one that this diameter is adequate for the passage of the nerve at all points even though the disk space is obliterated completely. Destruction of the adjacent surfaces of the vertebrae, however, which sometimes follows thinning of the disk can result in further narrowing of the vertical diameter of the intervertebral foramina sufficient to produce constriction of the nerve. On the other hand, the horizontal diameter may become inadequate for the nerve root if there is any encroachment on it by the disk. This diameter is smallest at the points of maximum lordosis of the spine, namely the lower cervical and lower lumbar regions, and is the result of the projection of the articular facets toward the floor of the canal. The poker spine, which is seen in both the lumbar and the cervical ruptured disks, is probably an attempt of the body to increase the distance from the facets to the disk and thus relieve the pressure on the nerve root.

We do not wish to infer that all cases which heretofore have been diagnosed as cervical rib or scalenus anticus syndrome are ruptures of the cervical disks. It is undoubtedly true, however, that an undetermined number of these patients have ruptured disks. Two of our cases were diagnosed elsewhere as scalenus anticus syndrome. On the other hand rupture of a cervical disk will cause spasm of the scalenus anticus muscle. (Note the spasm of the sacrospinalis and ilioband in ruptures of the lumbar disks.) The relief of symptoms following section of the scalenus anticus muscle in such cases might be explained on the same basis as the relief of pain from the Ober fasciotomy in the case of ruptured disk in the lumbar region.

Perhaps the most fascinating implication of this study is the possibility that many cricks in the neck are not, after all, the result of sleeping in a draft, some focus of infection or fibrositis, but are due to stretching or tearing of the annulus fibrosus of one of the cervical disks. Certainly in our 4 cases the numerous cricks in the neck of which these patients complained were in no way different from those seen almost daily. Perhaps it is not stretching the imagination too much to think that such a crick may be comparable to lumbago, which is doubtless the forerunner of ruptured disks in the lumbar spine in many cases.

Of all of the mistaken diagnoses made in this condition, that of coronary disease is most logical. It is not surprising that when a patient with agonizing pain in the heart and arm associated with extreme difficulty in breathing, presents himself, the first thought is of coronary disease. The fact that the 2 patients who are physicians believed in the beginning of the attack that they had coronary occlusion is most significant.

Of particular interest is the sensory disturbance resulting from pressure on the seventh cervical nerve root. The degree of sensory loss of the index finger in these cases is out of all proportion to that which we have seen elsewhere in the trunk or extremities when a single spinal sensory root has been sectioned. This suggests that the seventh cervical nerve root is almost entirely responsible for the innervation of this finger, in many persons at least. Such a conception is at variance with the work of Head,²⁰ Foerster²¹ and Sherrington²² and is subject to further proof. The pattern of the sensory disturbance of the seventh cervical root is also different from that described by Sherrington²² and Tilney and Riley,²³ being limited to the index and middle fingers without involvement of the thumb, the hand or the forearm.

The pathway of the radiation of pain to the precordial region is not definitely known. Nachlas¹⁴ suggests that the mechanism of the reference of this pain is as follows. The pathway is along the lateral anterior thoracic and medial anterior thoracic nerves, the former originating in the sixth and seventh cervical segments and the latter in the eighth cervical and first thoracic segments. Although these nerves are known to be motor nerves, it has been well established that such nerves possess protopathic sensation so that pressure on them will produce definite pain, diffuse in character but referable to the terminal portions of the nerve. This and other possible pathways of the radiation of this pain are being investigated at the present time.

Herniation of one of the lower cervical disks was suspected for several years before it was confirmed finally in our first patient (case 1) because the symptoms and physical manifestations were analogous in every respect to those caused by ruptures of the lower lumbar disks. We now believe that the diagnosis can best be made by clinical means alone and that the use of contrast mediums is unnecessary, as we have previously shown in the diagnosis of ruptured disks in the

lumbar region.¹ There is reason to believe that the percentage of error with contrast mediums will be even greater in the cervical spine than in the lumbar region. There are 3 causes for this: (1) The lesions are smaller, (2) they may be so far lateral that they are not in contact with the dura and (3) there is difficulty in filling the cervical canal with contrast mediums.

The presence of a unilateral rupture of one of the lower cervical disks is not in itself an indication for its removal unless it is causing incapacitating pain. Undoubtedly as this condition becomes more widely recognized many patients with pain less intense than that described here will be seen and will respond to more conservative measures. We recently have seen such a case which is not included in this report.

Unquestionably, the operative approach of choice is subtotal hemilaminectomy. It provides ample exposure and at the same time affords considerable protection to the spinal cord. It reduces also the postoperative soreness and possible weakness of the neck which might follow a complete laminectomy. We prefer local anesthesia in spite of the fact that there is some pain incident to exposure of the nerve root before it is injected with procaine hydrochloride. This anesthesia allows one to confirm the localization of the lesion before any bone is removed and affords further protection to the spinal cord. When the nodule of disk is exposed, only the loose fragments of fibrocartilage and those protruding from the disk space are removed. No attempt is made to curet out the remainder of the nucleus pulposus, as we do routinely in the lumbar region. Only the future will disclose whether this procedure is adequate for a permanent cure.

CONCLUSIONS

- 1 Unilateral rupture of the sixth cervical intervertebral disk produces a syndrome characterized by pain in the neck which radiates to the shoulder, precordium and arm and by sensory changes in the index and middle fingers.

- 2 The diagnosis of this condition can be made more accurately by clinical means than by the use of contrast mediums.

- 3 The operation of choice is subtotal hemilaminectomy under local anesthesia.

- 4 The localization of the lesion can be verified at operation before the removal of any bone.

- 5 Hypertrophic arthritis and/or narrowing of the intervertebral disk seldom causes nerve root pressure.

- 6 Rupture of any intervertebral disk may result in hypertrophic changes on the edges of the adjacent vertebrae.

- 7 The degree of sensory change in the index finger, which results from compression of the seventh cervical nerve root, in our experience, is more pronounced than that produced by interruption of any other single spinal nerve root.

- 8 The pathway over which the pain radiates to the precordium has not been ascertained.

- 9 An undetermined number of patients who heretofore have been thought to have coronary occlusion, angina pectoris, hypertrophic arthritis of the cervical spine, neuritis of the brachial plexus, bursitis, scapular anticus syndrome or cervical rib have a rupture of one of the lower cervical intervertebral disks.

THE USE OF PENTOTHAL SODIUM
ANESTHESIA IN THORACIC
SURGERY

HOWELL S. RANDOLPH, M.D.

AND

LESLIE R. KOBER, M.D.

PHOENIX, ARIZ.

The selection of an anesthetic for thoracoplasties presents a problem differing from that in other types of surgery in that the patient is more or less debilitated by long-standing infection and there is apt to be damage to the kidneys, liver and heart owing to the effects of prolonged toxemia or involvement with tuberculosis. The most important difference is the presence of infection in the lungs and the necessity of avoiding irritating inhalants which might in any way adversely affect the pulmonary lesions. The administration of ether by the drop method is not recommended because of its irritating effect on the mucous membranes. Beecher and Adams advocate its use by closed system apparatus (carbon dioxide absorption technic) and report 61 per cent pulmonary complications.¹

Infiltration of procaine hydrochloride and nerve block have the disadvantage that few patients escape without considerable shock and pain. The operation is prolonged and tissue resistance may be reduced, fostering wound infection. A spinal anesthetic has been successfully used by Ackman² with relatively low mortality and few complications, however, the hazard of this anesthetic bears less relationship to the condition of the patient, and it still seems that the margin of safety is low.

To have the patient under general anesthesia is desirable. Nitrous oxide, cyclopropane and ethylene are now most widely used. Each of these anesthetics has certain advantages and in selected cases may be preferred. We used procaine hydrochloride and the inhalation anesthetics in our work before 1935. However, we have come to use, more than any other, pentothal sodium without procaine, according to the following method.

TECHNIC

One and one-half grains (0.1 Gm.) of phenobarbital is given the night before operation. A light breakfast is frequently served two or three hours before the operation. One-eighth to $\frac{1}{8}$ grain (0.008 to 0.01 Gm.) of morphine is administered. We do not use pre-operative barbiturates because we feel that the more rapidly eliminated pentothal sodium works as well without them and that the postoperative recovery time may be delayed by them. Position and preparation of the patient is completed before the injection of 5 per cent pentothal sodium into the cubital vein is started. Blood pressures are checked. Two to 4 cc. of pentothal sodium is given, then a pause of sixty seconds or more permits the anesthetist to judge the patient's sensitivity. Usually 8 or 10 cc. is injected before the operation is begun, then 0.25 to 1 cc. a minute is given during the remainder of the operation as the patient's condition

indicates. The deepest anesthesia is often needed at the beginning of the operation to control the reaction to the cutaneous incision. The amount of anesthetic necessary to prevent coughing is usually about the amount needed to prevent movement of the patient and to maintain satisfactory anesthesia. Because of the patient's position constant vigilance is necessary to maintain a free airway. Rarely is a pharyngeal airway required but an attendant at the patient's head is desirable to maintain the position of the head and jaw. Oxygen is administered by nasal catheter if cyanosis appears, about half the cases requiring oxygen during the anesthetic. Seldom has nikethamide or metrazol been used, but a positive pressure apparatus should be available and has been useful on a few occasions. Administration of the anesthetic is discontinued five to ten minutes before completion of the cutaneous sutures, and the patient frequently moves on the table with the last sutures. The patient is placed on the operated side with a pillow under his head as he is returned to his bed. Intranasal oxygen is administered until the patient is sufficiently aroused to insure full respiratory movements. The patient is turned every few hours to encourage bronchial drainage. One thousand cc. of 5 per cent dextrose and 500 cc. of blood are administered in practically every instance. More intravenous fluids are not necessary in the majority of instances, since patients are rarely more than slightly nauseated for a brief period and fluid intake by mouth is adequate.

RESULTS

One hundred and twenty-three thoracoplasties performed on 53 patients with the removal of from two to six ribs have been reviewed in which the anesthetic agent was pentothal sodium. There were no operative deaths. The average duration of the operation was forty-nine minutes, the longest being one hundred and fifteen minutes and the shortest twenty minutes. The average amount of pentothal sodium used was 24 cc. Only 1 case required more than 40 cc., 50 cc. having been used in this instance.

Some degree of cyanosis was occasionally seen during the early stages of operation associated with light anesthesia, and sometimes breath holding or coughing, but this was always easily controlled by increasing the depth of anesthesia. Postoperative nausea was less than that noted following inhalation anesthetics, 5 patients had rather severe nausea, 45 had very slight nausea and 66 had none. It was thought that in many instances the nausea was due to the opiate rather than to the pentothal sodium.

Four patients had postoperative shock of rather severe degree, and minor degrees of shock were noted in several patients, but the impression gained in observing the patient's condition as he comes out of the anesthesia is that there is less tendency to the symptoms of falling blood pressure, rapid pulse and shortness of breath than is seen in the course of these operations following other anesthetics. The patient's awakening is gradual and not unpleasant, and there is less need for morphine to control pain during the first few hours.

One patient showed some necrosis around the cubital vein from extravasated pentothal sodium solution, and one experienced postoperative mental excitement with disorientation lasting several hours.

2 Ackman, Douglas. Results of Thoracoplasty in Advanced Pulmonary Tuberculosis. *Canad. M. A. J.* 45:422-425 (Nov.) 1941.

In 2 cases in which expectoration was profuse from empyema with bronchial fistula, pentothal sodium was found to be disadvantageous. Immediately after the pleura was opened the respirations became difficult, and it was necessary to aspirate mucus and pus from the pharynx and hurry the operation. As soon as the empyema pocket was emptied of pus, the patient's condition became less precarious. These patients might have done better under infiltration of procaine hydrochloride.

Roentgenograms were made after most of the stages of the operation, and immediately whenever early symptoms of dyspnea or pain in the chest plus physical signs indicated a possible atelectasis or any other complication.

There is apparently reduced incidence of postoperative spread, only 3 cases being noted in which spread of tuberculosis occurred within two months.

Atelectasis of a lobe occurred in 2 cases. In these 2 cases the atelectasis was on the same side as the operative procedure. In both cases the lung was found to be clear at the end of one month. There was 1 case of postoperative pneumonia which turned out to be spread of tuberculosis and left extensive residual disease in both lower lobes.

The incidence of postoperative atelectasis following a general operation under various types of anesthesia is given variously as follows: by Frias and Fernandez,³ 3 per cent in 556 cases, by Clegg,⁴ 2.14 per cent in 653 cases, by Elason and McLaughlin,⁵ 0.36 per cent in 8,864 cases, by Rovenstine and Taylor,⁶ 0.44 per cent in 7,874 cases and by Hand and Sise,⁷ 1.11 per cent in 180 cases. In thoracic surgery, Brunn and Brill⁸ report atelectasis in 4.82 per cent in 456 surgical cases and Berry⁹ 2.12 per cent in 188 cases. The percentage of atelectasis in our series was 1.7.

REPORT OF CASES

CASE 1—Atelectasis. C. F., a white man aged 27, height 5 feet 9 inches (175 cm), weight 135 pounds (61 Kg), had a history of tuberculosis for one year before operation. The amount of expectoration daily was 45 cc. There was moderate dyspnea with apparently asthma-like attacks. Physical examination revealed a fair general condition, preoperative x-ray examinations showed a cavity of moderate size in the central portion of the upper left lobe with considerable infiltration throughout the lobe. The lower lung was clear except for a few minimal small discrete shadows. A left phrenicotomy, five and a half months before, had resulted in moderate elevation of the diaphragm and fixation. Thirteen cc of pentothal sodium was administered before the operation was started, and a total of 24 cc was used. The pulse remained between 80 and 90 during the operation. There were 26 inches of ribs removed. The temperature rose to 103.6 F. the second postoperative day, the x-ray examination showed complete opacity of the left lung with displacement of the heart toward the left.

⁹ Berry F. B. Massive Atelectasis Complicating Paravertebral Thoracoplasty for Pulmonary Tuberculosis. *Arch. Surg.* 18: 257-270 (Jan. pt. 2) 1929.

Attempted aspiration failed to yield any fluid. One month later the lower part of the lung was found to be clear. Fixation of the left diaphragm undoubtedly favored production of the atelectasis.

CASE 2—Atelectasis. R. F., a white man aged 38, had had tuberculosis for seven years. Expectoration amounted to 60 cc daily and was positive for tubercle bacilli. There was a cavity 2 inches in diameter in the upper part of the left lung. Following removal of four ribs in the second stage of the operation atelectasis of the lower lobe on the left side developed, which cleared up in one month, and exceptionally rapid closure of the cavity was obtained and the patient was back at work in six months. The patient has been well two years.

CASE 3—Pneumonia followed by spread. B. S., a Negro woman aged 42, expectorated 30 cc of sputum daily, she had a cavity in the upper left lobe 3 inches in diameter. Removal of four ribs, 16 inches, in the first stage was followed by pneumonic consolidation of both lower lobes. Two months later x-ray examination showed partial clearing but extensive tuberculous shadows.

Of some interest in assessing the value of the anesthetic may be the late postoperative results. These, however, are so dependent on the classification of the patient's condition prior to operation that for purposes of comparison similar criteria must be utilized. Following the National Tuberculosis Association classification all but 1 of the 53 patients were in the far advanced stage. Twenty-eight were classed as bilateral, 8 of whom had collapse therapy of the lung contralateral to thoracoplasty. Seven had tuberculous empyema. Of those operated on more than six months ago, 50 per cent have arrested or apparently arrested tuberculosis. The condition in 16 per cent is quiescent, and that in 18 per cent is classified as unstable, in half of which there is improvement. Fifteen per cent of the patients have died; 2 patients within two months. Of these 2, 1 died of wound infection and the other a very poor surgical risk, of reduced vital capacity and insufficient cardiac reserve. Five died in from one to six years.

COMMENT

Certain attributes are desired in an anesthetic for thoracoplasty. First, the anesthetic must be nonirritating to the respiratory tissue. We have found that patients coming out of the anesthetic following pentothal sodium have no hypersecretion and there is no change in the character of the sputum.

With other types of anesthesia patients usually go through a period of excitement during which secretions may be dislodged and coughing may be troublesome. During surgery hyperventilation of the lung with excessive mobility is to be avoided. This is accomplished better with pentothal sodium than with any other anesthetic. In fact the depression of respiration is apparently an advantage in that it prevents dislodgment of purulent material which may be present under the operative site.

To attempt to give any anesthetic so lightly that the cough reflex is not abolished is unsatisfactory because the half-hearted attempts of the patient to free himself of sputum when semiconscious may do more harm than good.

Electrocoagulation is found very useful in accomplishing hemostasis. Failure to dry the wound carefully before final closure delays wound healing and makes for a greater chance of the wound breaking down.

and becoming infected. Several minutes may be cut from the operating time by using electrocoagulation.

Several minutes may also be saved in the induction of anesthesia since pentothal sodium provides surgical anesthesia within two or three minutes after it is started.

The absence of postoperative nausea constitutes an advantage which we consider extremely important in combating the discomfort and shock of the operative procedure. It is hardly necessary to point out that if one starves a normal, healthy person for twenty-four hours considerable weakness results. If this is added to the effects of the operation, delayed recovery is to be expected. With pentothal sodium, a small breakfast given two or three hours before operation seems perfectly safe, and many patients eat solid food within two hours after the operation, and most of them eat the regular evening meal. Patients' spirits are correspondingly good the evening of the operation.

Awakening from this anesthetic is more like awakening from a night's sleep than from an artificially imposed anesthesia, and when operative procedures require repetition—sometimes five or six stages—the patient's morale is less likely to be destroyed than with an unpleasant anesthetic experience.

We believe that pentothal sodium is to be recommended for thoracoplasty.

Clinical Notes, Suggestions and New Instruments

NEUROFIBROMA (NEURINOMA) OF THE FOOT

EMIL D. W. HAUSER, M.D. CHICAGO

An 11 year old girl was brought in Aug. 2, 1939 because of pain in the ball of the right foot, which had been present for six months. The family physician had taken roentgenograms, which were negative, and he was of the opinion that she had a calcified bursa on the plantar surface of the foot. With no improvement after six months the parents consulted another physician, who referred her to me. She gave a history of having had pyelitis and on getting up after prolonged bed rest the foot was painful. She also had had some callus form under the anterior arch, which had since disappeared. There was some pain in the region of the longitudinal arch.

Examination showed a definite tumor on the plantar surface of the foot which was very tender. This tumor was beneath the shaft of the first metatarsal bone and was felt to be about the size of a bean. The possibility that this might be a ganglion was considered. She also had a slight valgus deformity and a slight lowering of the arch of the right foot. It was thought that she had some foot strain with beginning pes valgoplanus. The foot strain was relieved by means of adhesive strapping, but the pain and swelling beneath the head of the first metatarsal bone did not subside. Surgery was advised. The possibility that this might be a glomus tumor, neuroma fibroma, ganglion and inflammation of the bursa with calcification was considered.

Under ethylene anesthesia the tumor was exposed and a small, encapsulated tumor, about $\frac{1}{2}$ inch in diameter, was removed. It was found to be attached to the plantar fascia. The tumor contained a thick mucinous-like material. At the time of operation it had the appearance of a small ganglion. The report of Dr. Donald O. Manshardt, pathologist, stated

that the tumor consisted of irregular shaped, firm cauliflower-like, white tissue. Intermingled strands of what appeared to be adult connective tissue were found in these sections. In places these were in poorly formed whorls in which there was some suggestion of palisading of nuclei. Rarely there was definite palisading. There was also some hyalinized connective tissue which divided this more cellular tissue into capsules or poorly defined bundles. About the periphery of these areas there were smaller clusters of cells, arranged in whorls, which superficially resembled the psammomatous type of meningioma except that there was no calcification. These whorls occurred in long channel-like formation, composed of interlobular connective tissue. The entire structure resembled nerve in its architectural configuration. No normal nervous elements were seen.

The diagnosis was made of a large neurinoma from the plantar region of the right foot. (Note: The term "neurinoma" avoids the implications as to the origin of the tumor cells suggested by "neurofibroma" or schwannoma.) The wound

Fig. 1—Operation for neurofibroma of the foot.

healed without any difficulty and pads were placed in the shoes to avert any further development of foot strain. The child stayed free from symptoms until six months later when she again noticed pain and tenderness underneath the arch of the right foot.

The pain increased, so that on June 7, 1941 she returned for examination. At this time the slightest pressure over the plantar surface beneath the navicular bone caused intense pain. There was a definite fulness in this area which was visible and palpable.

In view of the fact that previously a neurofibroma had been removed from this foot it was thought that a similar tumor might have occurred higher along the nerve. She entered the hospital on June 11, 1941 for operation. A longitudinal plantar incision was made and a small area of fibrous tissue was found where the previous tumor had been removed (fig. 1). The plantar fascia was distended and a tumor could be felt beneath it. The plantar fascia was incised and a large tumor the shape of a sausage was exposed. It consisted of a lobulated soft mass which was well encapsulated. The tumor was easily dissected from the tendon sheaths in the area and was traced up until it ended in the deep plantar nerve. Normal ne

tissue was seen to end where the tumor started. The plantar fascia and skin were closed. Convalescence was uneventful and the patient left the hospital in about twelve days. There was a slight amount of paresthesia in the area of the operation.

Fig. 2—Low power section of tumor stained with hematoxylin and eosin. A, large whorls; B, section taken for figure 3.

Fig. 3—Section slightly reduced from a photomicrograph with a magnification of 85 diameters, stained with hematoxylin and eosin. A, blood vessel; B, proliferation about nerve axons; C, palisades of nuclei.

Dr. Manshardt's report on the specimen stated that the tumor was a large, elongated, firm, encapsulated, pearly white mass whose external surface was loosely lobulated and irregular (figs. 2, 3 and 4). The mass measured 6.5 by 2 cm. On the

cut surface there were numerous circumscribed gray white whorls of tissue. Two blocks, six sections, were made. The first block was of a well encapsulated lobulated mass of tissue composed of cells having large, vesicular, elongated nuclei of oval or spindle shape. These were arranged in large concentric whorls with rather abundant mucoid intercellular substance. The cells were rather uniform in appearance throughout the section. In some regions small concentric whorls were seen, but for the most part the tumor cells were rather loosely arranged showing a slight tendency toward palisading of the nuclei. There were no areas of increased density, increase in mitotic figures or invasion of the capsule to indicate that the tumor might be malignant.

Sections stained with van Gieson's stain showed the presence of a moderate amount of collagen in the tumor. Davenport's nerve fiber stain revealed the presence of occasional nerve fibers. In the area pictured in figure 3 (magnified 85 times) a nerve

Fig. 4—Section magnified 660 times, stained with hematoxylin and eosin. A, mucinous intercellular substance; B, neurinoma cells.

fiber is found at the center of each of the small whorls surrounded by concentric layers of cells. Diagnosis was made of a large neurinoma from the plantar area of the right foot. Ewing¹ states that this type of tumor affects mainly the larger nerve trunks and occurs in nearly all parts of the body, forming encapsulated slowly growing firm or soft masses attached to the nerve trunk. They have a definite tendency to recur locally from remaining tumor tissue if not completely removed and may become malignant and locally invasive following recurrence. It is rather common to find a new tumor develop higher up in the nerve trunk. This may be the result of a new growth or extension of the original tumor cells within the epineurium.

A neurofibroma of the deep plantar nerve is a rare tumor. Neurofibromas have been reported in many nerves of the body, and it is not unusual to have recurrences in the nerve proximal to the original tumor, as was seen in this case. The possibility of another recurrence higher up with more serious complica-

tions must still be kept in mind. The patient has been kept under observation for two and one-half years after the second operation and has shown no sign or symptom of recurrence, so that the possibility of recurrence has become quite remote.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

E & J RESUSCITATOR, INHALATOR, ASPIRATOR (FOX MODEL) ACCEPTABLE

Manufacturer: E & J Manufacturing Company, 139-141 South Verdugo Road, Glendale, Calif.

The E & J Resuscitator, Inhalator and Aspirator, Fox Model, is designed to be used in emergencies in which natural respiration has failed with resulting asphyxia. It is similar in operation to the E & J Resuscitator and Inhalator which was accepted by the Council (THE JOURNAL, May 13, 1939) for use only by professional or other adequately trained personnel. In construction the Fox Model is different from the earlier one in that a venturi is used in place of the piston to create the suction; it is available in portable and hospital models.

In the Council's investigation of the apparatus it was found that the unit was sturdy in construction and appeared to be capable of withstanding ordinary wear and tear. There are yokes to accommodate two high pressure oxygen cylinders, or cylinders of mixed gases (sizes A to E). A pressure gage which registers the approximate pressure of gas in the open cylinder serves to warn when the cylinder is becoming depleted.

Mechanically, the E & J Resuscitator, Inhalator and Aspirator, Fox Model utilizes gas pressure in the cylinder to control delivery of (1) alternating positive and negative pressure through two tubes to the face mask, (2) constant flow of oxygen (or any gas mixture) to the face mask and (3) negative pressure said to be equal to 16 ounces per square inch, available in a separate tube designed to suck mucus from the air passages to a trap bottle furnished with the apparatus. Three positions of a lever determine which one of these three functions is in action at a given time. No two can be available simultaneously. The intricate mechanism which secures negative pressure for suction and for the expiratory phase of artificial respiration apparently is operated on the so-called Venturi principle, after the fashion of the steam injector or a Chapman vacuum pump. The manufacturer claims that positive pressure of 13 mm of mercury and 9 mm of mercury negative pressure is delivered to the mask alternately. Experiments with the model submitted have verified this claim to be substantially correct. Variations did not exceed 2 or 3 mm of mercury under varying conditions in human subjects. Investigations included records made of pressure in the bronchus when no respiratory activity of the human subject was present. These positive and negative pressures are permanently adjusted at the factory and cannot be changed by the operator. The actual negative pressure for suction corresponds to that claimed in the pamphlet. It can be asserted that the apparatus furnishes adequate pulmonary ventilation provided airtight contact of the mask is maintained with a patient whose air passages are unobstructed. The positive and negative safety flow-off valves are set at 18 mm of mercury.

The masks for an adult and an infant are adequate for the purpose. They are provided with an exit valve which is easily closed tight during use of the machine for artificial respiration and, when opened, acts freely when the lever is in the position for inhalation of oxygen by the patient. An inlet valve at the machine end of the connecting tubing permits inhalation of

environmental atmosphere if the supply of gas in the cylinders becomes exhausted during use of the "inhalator".

It is obvious that negative pressure to provide suction of foreign liquids from the respiratory tract is desirable for depressed patients. Two characteristics of such negative pressure are important: (a) actual pressure provided, (b) the volume of atmosphere moved at this pressure in a given time. To remove vomitus or other fluids quickly and safely the actual negative pressure should be moderate and the volume of atmosphere sucked in a given time should be maximal.

It can be stated that the Fox Model E & J Resuscitator does what is claimed for it, namely, it maintains adequate pulmonary ventilation when properly used. The term "Properly used" means that the mask is kept in airtight contact with the face and that the air passages are free of obstruction.

The evidence that has been made available indicates quite clearly that the machine has demonstrated its worth in trained hands. The critical data consisted of many reports on the use of the resuscitator in the fields of surgery and obstetrics.

It must be pointed out, however, that the process of blowing oxygen into the lungs and aspirating it has a reverse effect on the circulation from that of normal respiration. Normal respiration tends to facilitate the exchange of gases in the lung capillaries. When the lung is inflated, even at very moderate pressures, circulation through the lung capillaries is retarded for an instant, since the blood pressure in these capillaries is very small. Stoppage here necessarily affects the entire circulation. However, periodic stops last only a moment, since the peak pressure (14 mm of mercury) is maintained for only a short part of the cycle.

Another point should be borne in mind. While artificial respiration has been maintained by systems of this type in physiologic laboratories where experiments are performed on animals with the chest opened, the pressure required for adequate ventilation in such cases is much less than that required to distend the lung when the diaphragm must be forced down against the pressure of the abdominal contents and the bony thorax distended by pressure exerted by the lung from within.

In accepting the apparatus, the Council wishes to stress two points: (a) No artificial resuscitator or inhalator should replace the training of medical men and first aid men in the prone pressure method of resuscitation, (b) it is very important that this machine be used by well trained operators who have received their instruction from competent physicians.

The acceptance of this apparatus therefore is not to be regarded as a recommendation to abandon prone pressure methods of artificial respiration. In cases needing resuscitation the prone pressure method should be instituted immediately pending the arrival of any type of resuscitator, inhalator or respirator, provided the patient's condition permits.

It is manifestly impossible to apply prone pressure artificial respiration in all conditions which arise in medical practice as instanced in surgical operation on the abdomen when respiration fails. In such cases a mechanical resuscitator device for maintaining artificial respiration over short periods may be very desirable. Operators who are trained to use the mechanical resuscitator should also be equally well trained in the prone pressure method of artificial respiration.

The Council on Physical Therapy voted to accept the E & J Resuscitator, Inhalator, Aspirator Fox Model, for inclusion in its list of accepted apparatus with an understanding of the limitations and hazards of positive pressure resuscitators with the expectation that it will be used only by professional or other adequately trained personnel.

FURTHER EXPERIMENTAL STUDIES OF BLAST INJURIES

The basic experiments of Hooker and of Zuckerman demonstrated that the effects on the body of explosions both in air and in water are primarily due to the externally applied pressure wave. Williams¹ observed that pressures set up by an explosion at some depth in water create a new factor. When the pressure wave reaches the surface, transmission of the pulse to air does not occur but there is reflection as a wave of tension at an angle equal to the angle of incidence. The human body, according to Williams, has roughly the same density as water. When the pressure wave impinges on the body reflection does not follow but the pulse will be transmitted through the tissues without displacement just as if the body were so much water. However, when the transmitted pulse encounters an air cavity in the body as, for example, the lungs, the static wave of pressure will change into a wave of kinetic energy in the layers of tissues lining that cavity and a disruptive effect will occur. Hence the lungs and other gas filled cavities in the body are particularly susceptible to damage from the pressure wave even though the body itself may not be deeply immersed.

Greaves and his associates² exposed rats and guinea pigs to explosions of tetryl (dinitrophenylmethylnitramine) in a welded steel tank 70 by 48 by 42 inches filled with water. The charge was detonated 20 inches below the surface while the animals were swimming within a 2 foot circle beyond the point directly over the charge. Goats were exposed to the effects of a 300 pound depth charge exploded 50 feet below the surface in water 100 feet in depth. Lethal, sublethal and minimum lesions were induced and studied. The lesions in the lungs included diffuse hemorrhage

throughout the entire parenchyma. Microscopic studies of these lesions revealed that the first evidence of injury was rupture of the capillaries and hemorrhage into the interalveolar septum. Similar observations were reported by Cameron, Short and Wakely.³ Two types of lesions were seen in the gastrointestinal tract in the lethal cases: hemorrhagic discolorations of the bowel wall and perforations. Both types were definitely related to the presence of gas within the lumen. When 20 cc of air was injected into the peritoneal cavity of a rat which was then subjected to a lethal underwater blast laceration of the liver and spleen and extensive hemorrhage into the abdominal wall resulted. Injuries of these structures were not seen when normal animals were blasted. Four short segments of normal rabbit intestine were removed and ligated at both ends after the first was completely collapsed, the second filled with air, the third with isotonic solution of sodium chloride and the fourth with air and saline solution. They were then submerged and subjected to underwater blast. The collapsed segment and the one filled with saline solution were unaffected but the two containing air were ruptured. These investigators also found that kapok and foam rubber are best capable of preventing or minimizing the injurious effects of the compression wave in the experimental animals.

Both clinical and experimental evidence has established that immersion blast produces abdominal trauma in addition to the chest lesions seen in air blast. Friedell and Ecklund⁴ were particularly interested in factors which lead to the production of intestinal perforation. They attempted to determine by animal experiments whether the perforations occurred immediately or were the delayed effect of severe intestinal trauma. Reports of hemorrhagic areas in the bowel following blast injury created the impression that the hemorrhage was followed by necrosis of the wall with perforation and peritonitis. Experiments were performed in a large steel tank measuring 8 by 6 feet filled with water to a depth of 4 feet. Postmortems on guinea pigs which died immediately or shortly after exposure in a water filled tank to a blast caused by detonating caps containing a charge of 35 grams of fulminate of mercury revealed that the abdominal wall was uninjured but that there were areas of subserous hemorrhages over the colon and small bowel and especially over the enlarged appendix. Most serious changes were noted over fecal collections. The lungs had symmetrical hemorrhagic areas. Microscopic studies did not reveal perforations of the intestinal tract. Abdominal lesions were not pro-

⁴ Friedell M T and Ecklund A M. Experimental Immersion Blast Injury. *U S Nav M Bull* 41 353 (March) 1943.

duced except when the lungs were so severely damaged that death ensued. To eliminate the severe lung injury these investigators devised a chamber which minimizes the effects of blast on the thorax. With this chamber the lungs were protected so that previously fatal explosive conditions were no longer lethal. The abdominal lesions were present, however, and as the force of the charge seemed to grow greater the hemorrhagic lesions gave way to perforations.

In the cases observed by these authors at the hospital it was felt that possibly the life jacket prevented such severe injuries to the lungs as to cause death and that the abdomen, which was unprotected, bore the brunt of the explosion. This seems to be borne out by their experiments in which the previous lethal condition was repeated except that the chest was protected. Perforations were then found in the intestinal tract, and the animal survived the immediate explosion. They therefore conclude that the perforations are an immediate result of the blast and do not occur later as a result of necrosis of the bowel wall. These perforations therefore demand early surgical intervention, hemorrhagic lesions do not require surgical treatment. It is suggested that extension of the life jacket to cover the abdomen would be beneficial. The authors did not find evidence in their experiments that water was forced through the anus with rupture of the bowel. The lesions seemed to be a direct effect of the explosive force transmitted through the elastic walls of the abdomen and thorax.

Observations on the occurrence of intracranial trauma following blast injury are few. Unfortunately Wilson and Tunbridge⁵ did not have opportunity to examine the brain and spinal cord in their necropsies on 12 persons who died as a result of blast injury. In Ascroft's⁶ fatal case of multiple injuries due to the explosion of a hand grenade at short range, in addition to the extensive infiltration of the lungs, a peculiar discoloration of large areas of the cerebral hemispheres was found as the result of the great numbers of minute hemorrhages confined to the gray matter of the cortex. This observation seems to be unique. The lesion did not resemble any hitherto described as following death from blast. Zuckerman reported pial hemorrhages on the surface of the cortex and hemorrhages from the tela choroidea, but hemorrhages did not occur in either the gray or the white matter of the brain in monkeys subjected to blast pressures as high as 110 pounds per square inch. Friedell and Acklund did not note hemorrhages into the brain in their experimental animals which died primarily as a result of a blast. They felt that a blast wave sufficiently forceful to produce

intracranial trauma would with certainty cause fatal lesions of the intrathoracic and intraperitoneal structures.

Abbott, Due and Nosik⁷ call attention to a small group of patients with a history of exposure to severe concussion, loss of consciousness for a period varying from a few minutes to several days, persistent headaches, memory loss and irritability. Positive neurologic signs are minimal. The most common are a slight facial palsy, a transient hemiparesis and occasionally a transient change in reflexes. There is a history of coma, syncope or convulsions which did not exist prior to the blast and a definite departure from a stable personality. Such patients are often regarded as having a functional disturbance—a psychoneurosis or traumatic neurosis. These authors advance the idea that these symptoms are characteristic of a subdural hematoma or a subdural effusion. Pneumoencephalography will demonstrate a characteristic filling defect over the cerebrum in these cases with a distortion of the ventricular system in some. A trephine opening over the indicated superior temporal area, with incision of the dura, will permit the escape of either old blood or xanthochromic fluid. Of 10 cases in which this procedure was performed, 7 resulted in subdural effusions, 2 were instances of subdural hematoma and 5 were bilateral. There were no operative fatalities. The symptoms were promptly relieved. The last quoted reports suggest that cerebral lesions must be taken into consideration as possible direct or contributing factors in the mechanism of death in blast injuries and as a cause of certain late complications, such as subdural hematoma and subdural effusion.

Obviously, the difficulty of diagnosis in such obscure conditions should not be increased by a too liberal use of narcotics. Surgeons have suggested that morphine is contraindicated in the acute phase of blast injuries because it tends to accentuate the pulmonary edema and obscures the symptoms of abdominal and cerebral complications. Its use would seem to be justified only in the presence of painful injury or excessive restlessness.

The numerous reports now appearing in medical periodicals and the many unanswered questions that are being raised relative to the effects of blast on various systems in the human body indicate the need for further investigation, both clinical and experimental. The approach through special committees or subcommittees of the Office of Scientific Research and Development and the Division of Medical Sciences of the National Research Council, which has been so successful in other problems, might well be applied in the case of blast.

Current Comment

PLANS FOR THE WAR BLINDED

Among the casualties of war few merit more immediate consideration than that given to those who become sightless as a result of their participation in the national defense. In World War I, according to available figures, less than 250 Americans were blinded. Thus far the number of British soldiers who have become sightless, including the men from Great Britain and the colonies, is somewhat less than a few hundred. Planning bodies, therefore, estimate that the number of Americans in the armed forces who become totally blind will not exceed a few hundred. For the past six months representatives of the Surgeon Generals of the Army, the Navy and the Public Health Service, the administrator of the Veterans Administration, the Federal Board of Hospitalization and the ophthalmologic committee of the Division of Medical Sciences of the National Research Council have been engaged in a study of the problem. An elaborate program has been developed to rehabilitate socially and economically those who become sightless. Sufficient funds have been provided by the Congress to meet every possible need. The plans contemplate utilization of existing agencies which deal with the blind. However, public fund raising campaigns are unnecessary since the over-all need is hardly sufficient to demand special expansion for this purpose in the services of unofficial agencies. In accordance with the executive order of the President, the social rehabilitation of the blind becomes a function of the Veterans Administration and is to be handled by the Division of Educational Rehabilitation and not the medical division. Through the cooperative effort now in process of development the rehabilitation will begin just as soon as the diagnosis is made and will continue from the time of reception of the invalid by the armed forces until the man can be discharged from the Veterans Administration physically, mentally and socially rehabilitated.

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the sixth time at the meeting on Tuesday night, June 8, in the ballroom of the Palmer House, Chicago, during the regular session of the House of Delegates of the American Medical Association in Chicago, beginning June 7, 1943. The medal was awarded, for the first time, in 1938 to Dr. Rudolph Matas of New Orleans, in 1939 to Dr. James B. Herrick of Chicago, in 1940 to Dr. Chevalier Jackson of Philadelphia, in 1941 to Dr. James Ewing of New York and last year to Dr. Ludvig Hektoen of Chicago. This award is recognized as one of the most distinguished honors within the gift of the American Medical Association. Any Fellow of the Association may submit nominations, which should be sent, together with a record of the scientific services of the nominees, to the chairman of the Committee on Distinguished Service Award, Dr. A. A. Walker, 2250 Highland Avenue, Birmingham, Ala., or to the Secre-

tary of the Association at 535 North Dearborn Street, Chicago. Of all nominations received by the committee, five are submitted to the Board of Trustees of the Association, from which the Board selects three to be submitted to the House of Delegates at its first meeting at the time of its regular session. Immediately on submission of the nominations by the Board of Trustees, the House of Delegates by official vote selects the recipient of the honor, to whom the Distinguished Service Medal is presented at the meeting at which the President-Elect is installed as President, which is usually on Tuesday evening of the week of an annual session. An extended list of distinguished physicians nominated for this award will enable the committee, the Board of Trustees and the House of Delegates all of whom participate in the selection, to determine for 1943 a recipient of distinction, whose nomination will reflect favorably on himself and on the Association.

LEGAL MEDICINE IN PHILADELPHIA

The coroner of the county of Philadelphia, the first physician to hold the office since 1878, has developed a program that may be expected to increase the efficiency of his office and will in addition contribute materially to the dissemination of knowledge of the subject of legal medicine. In an effort to put the functioning of his office on a scientific, efficient basis he has created an advisory board consisting of the president of the county medical society, the director of legal medicine at Temple University, a professor of sociology who is also an authority on criminology, an associate professor of medicine, and the president of the College of Pharmacy. Special consultants have been named who will be able to bring to the work of the coroner's office specialized knowledge whenever the occasion demands, consultants in toxicology, consultants in ballistics and consultants in medical and legal research. Realizing the potential value for purposes of instruction of the material that passes through his office, the coroner has formulated a plan under which the six medical schools of the city may have access to that material by conducting classes each week in the morgue. A series of lectures on legal medicine under his direction has recently been concluded. The lectures were given in the headquarters of the Philadelphia County Medical Society under the sponsorship of that society, the six medical and two law schools, the bar association, the College of Pharmacy and the office of the district attorney. The lectures were well attended by medical, law, pharmacy and police students and by physicians and lawyers. No admission charge was made. A tentative selection has been made for a similar series to be given in the fall, and plans are being considered to repeat the program annually. In integrating as he is the various groups in the community that should be concerned in the development and dissemination of knowledge of legal medicine and in associating the coroner's office so intimately with that development, Dr. Herbert M. Goddard may well be constructing a pattern that will be followed elsewhere.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

ARMY

INTERNS AND RESIDENTS IN AIR FORCE HOSPITALS

Policy to Be Followed in Placing Present Interns and Residents Who Will Be Assigned to the Army Air Forces

Those interns and residents who are ordered to duty with the Army Air Forces are to be given a period of training which will augment the training received in civilian life. The first six months of this training will have a distinct military character and will be carried out as follows:

1 A policy of indoctrination and assignment of interns and residents entering the Army Air Forces is to be established in specified Army Air Force hospitals.

2 The purpose of this plan is to acquaint the newly assigned officers with army hospital routine and to give them further concentrated professional training. Such placement will materially aid the permanently assigned officers in the Army Air Force hospitals with their routine work.

3 The program will function as follows:

(a) Men will be assigned from Carlisle Barracks to designated Army Air Force hospitals by the Air Surgeon at the approximate ratio of 15 officers per hundred hospital beds.

(b) These officers will serve as junior assistants for a period of approximately six months in the larger hospital installations.

(c) These junior officers will be assigned to ward work under a senior officer, preferably one who has had some teaching experience or who is personally adaptable to teaching. He will act as consultant and adviser for the junior officer or officers under him. The junior officer will keep records, make physical examinations and take over all routine work under the direction of his senior officer.

(d) The detailed division of training should be approximately as follows:

(1) Routine ward work, five hours daily (example: 0800 to 1200, routine work, 1600 to 1700, afternoon ward rounds).

(2) Drill or physical education, one hour daily.

(3) Lectures on x-ray, laboratory, medical, medical administrative or military subjects, two hours daily. In this period could be included firing on the range and work with field units.

(e) Regular staff conferences should be held at specified times covering x-ray, electrocardiography, clinical pathology and general medical and surgical problems.

4 The general division of time in the six months training period for junior officers will be divided approximately as follows and the men should rotate through the entire service whenever possible:

	Per Cent
Medical service	40
Surgical service	20
Dispensary service	10
Eye, ear, nose and throat service	10
X-ray service	10
Venereal disease control and immunization	10

5 Junior officers will be graded weekly by their consultants and at the end of a six months period a final grade will be given to each junior officer by the post surgeon. Professional ability, adaptability to army routine and qualities of leadership will be considered in the final evaluation. Military necessities permitting, the upper third of the class will be allowed to choose between a second period of six months in a preferred straight residency in the same hospital installation or of being assigned to the School of Aviation Medicine, preference of service being

given in the order of class rank. The remaining members of the class will then be assigned, by the Air Surgeon, to smaller hospitals serving the flying fields, in order that they may gain some first hand knowledge of this type of service. After an additional period of service at this type of installation they will be further classified for the School of Aviation Medicine or a general duty assignment. Residents whose civilian training has been interrupted will when possible continue training in that specialty.

6 This program is designed to mature the younger medical officers more quickly and to utilize their efforts in the best way possible from the onset of their assignment. Such utilization under supervision, will relieve the senior officers from much of their routine work and release them for more important professional duties. The junior officers thus assigned should profit tremendously by the experience and personal guidance of their seniors.

TRAINING FOR FIELD WORK

Three hundred and twenty-two more officers of the Medical Department qualified on March 11 for duty with medical units in the field when they were graduated from the Medical Field Service School at Carlisle Barracks, Pennsylvania. The officers completed six weeks of grueling training. These experienced physicians, dentists and sanitary engineers left immediately after the exercises for their respective units. The training course here in medical field work taught them the military knowledge necessary for them to be efficient Medical Department officers, capable of carrying out medical preventive measures and caring for the sick and injured under war conditions. The subjects taught included training medical support tactics, military sanitation, logistics, field medicine and surgery, and administration presented in an intensive six weeks program of daily lectures, home study and field demonstrations.

AT A JUNGLE FIRST AID STATION IN PANAMA

An army doctor at a jungle outpost in the Panama Canal Department is a military tactician as well as a physician, as with his help it is possible to maintain gun and searchlight positions in the jungle. The officers and enlisted men of the medical department have hacked their way through the jungle, built first aid stations and are largely responsible for the lowest malaria rate in the history of the Army in Panama. Ambulances can now reach many of these positions to bring in soldiers requiring hospitalization, while formerly litter bearers had to carry a sick man for miles. Army doctors attached to one Coast Artillery unit still must travel 225 miles a day to cover a few of the emplacements in the jungle. These officers daily look for mosquito breeding places. Continuously they move first aid stations into different positions in the jungle. A first aid station which can be packed into two trucks is built near emplacements. Emergency operations can be performed at a moment's notice in these aid stations. One jungle position for over a year has had a perfect sanitation record, and not one man has had malaria. Occasionally natives living in the jungle call at first aid stations to be treated. The dentists who visit the emplacements regularly carry their equipment in a trunk containing a folding steel chair, foot engine and surgical dental equipment. The biggest problem confronting the jungle medical detachment now is transportation. The positions are so tattered that much time is taken up by traveling.

THE VALLEY FORGE GENERAL HOSPITAL

One hundred and sixty-five years after General Washington made his famous encampment at Valley Forge, the new U S Army Valley Forge General Hospital was officially opened, February 22, at Phoenixville, Pa., which is only a short distance from the historic region. This vast army hospital has a capacity of about 2,000 beds in two story brick structures connected by hallways. The commanding officer of the Valley Forge General Hospital is Col Henry Beeuwkes of Jamesburg, N. J., honor graduate of the Army Medical School in the class of 1909 and personal physician to General Pershing during the first world war. Colonel Beeuwkes later resigned his commission in the Army to become associated with the International Health Board of the Rockefeller Foundation and for many years carried on research in yellow fever for that organization in Africa. The administrative work of the Valley Forge General Hospital is carried on by twenty-three medical administrative, quarter master engineer and finance officers.

As of March 15, the professional staffs of the hospital were as follows:

EXECUTIVE AND ADMINISTRATIVE SERVICE

Col Henry Beeuwkes commanding officer
Lieut Col Robert D Smith executive officer
Major Alfred G Gillis director of medical training
Major Arthur Heyman director of dietetics
Major Bernard M Murphy receiving and disposition officer

MEDICAL SERVICE

Lieut Col Marshall A Fulton chief of medical service
Major Maurice A Schmitzer assistant chief of medical service and chief of general medical service
Major Seymour Fisher station surgeon and outpatient service
Major Samuel Morrison chief of gastrointestinal section
Capt Louis K Alpert chief of cardiovascular renal section
Capt Michael J Lepore chief of officers and women section
Capt Raymond J Rickloff chief of communicable disease section and consultant in dermatology
Capt Russel W Lyster, assistant chief of general medical section
Capt Paul A Morrow assistant chief of communicable disease section
1st Lieut Loren F Blaney ward officer cardiovascular renal section
1st Lieut Allen S Cross ward officer officers and women section
1st Lieut Elliot D Giddon ward officer general medical section
1st Lieut William G Layton ward officer communicable disease section
1st Lieut Dean Rizer ward officer cardiovascular renal section
1st Lieut Robert E Westmoreland ward officer gastrointestinal section

SURGICAL SERVICE

Lieut Col Ralph J Haws chief of surgical service
Major Charles M Robbins assistant chief of surgical service and chief of general surgical section
Major Spencer T Snedcor chief of orthopedic section
Major Irvin S Koll chief of urologic section
Major Charles W Boyd chief of eye ear nose and throat section
Capt Albert J Abbot ward officer eye ear nose and throat section
Capt John M Borbonus chief of officer and women section
Capt Merian Gearhart ward officer, general surgical section
Capt Philip E Lear ward officer general surgical section
Capt Charles D Lenhoff ward officer urologic section
Capt Willis H McKean ward officer general surgical section
Capt Phillip J Morgan ward officer general surgical section
1st Lieut Francis L Coffey ward officer orthopedic section
1st Lieut Walter C Graham ward officer orthopedic section
1st Lieut Clinton A Hays chief of septic surgery
1st Lieut George E Lowery chief of physical therapy
1st Lieut Stephen M McCoy ward officer officer and women section
1st Lieut Karl S Russell chief of operating and anesthesia section

NEUROPSYCHIATRIC SERVICE

Capt Walter E Barton chief of neuropsychiatric service
1st Lieut Dallas Pratt ward officer neuropsychiatric service
1st Lieut Daniel S Jaffe ward officer neuropsychiatric service

X-RAY SERVICE

Capt John Francis Miller chief of x-ray service
1st Lieut Edward H Gregman assistant chief of x-ray service

LABORATORY SERVICE

1st Lieut Hans G Schlumberger chief of laboratory service
1st Lieut Robert D Johnston assistant chief of laboratory service
2d Lieut Edmund P Finch laboratory service

DENTAL SERVICE

Lieut Col Pope B Holliday chief of dental service
Major George R King assistant chief of dental service
Capt John C Breuker Jr., dental officer
1st Lieut Robert E Connell dental officer
1st Lieut Michael L Di Napoli dental officer
1st Lieut Julius Eingorn dental officer

VISIT BY GENERAL MORGAN

Brig Gen Hugh Jackson Morgan, Medical Department who was professor of medicine at Vanderbilt University, Nashville, Tenn., before called to duty as chief consultant in medicine in the Surgeon General's Office, Washington D C on March 10 completed a visit at Carlisle Barracks, Pennsylvania, to study the work of the Medical Field Service School and the Medical Department Equipment Laboratory. General Morgan addressed the three basic officers classes on "The Mission of a Medical Officer." He was accompanied by Lieut Col B Noland Carter, Medical Corps, assistant to the consultant in surgery in the Surgeon General's Office. In the first world war General Morgan a senior at Johns Hopkins University enlisted for service with Base Hospital No 18 and was sent overseas in the American Expeditionary Forces. In May 1918 he was commissioned a first lieutenant in the Medical Corps at Longres France. Colonel Carter was assistant professor of surgery at the University of Cincinnati before being called into military service about a year ago.

NUTRITION PROGRAM AT WRIGHT FIELD

A display of nutrition exhibits prepared by Dr Bruno Gebhard and lent by the Cleveland Health Museum is the first step in a campaign designed to increase the efficiency of workers and reduce sickness absenteeism at Wright Field Ohio. The opening phase of the campaign came with the announcement of food rationing and it has given field workers information on selecting nutritious food within the rationing limits.

Illustrated in the exhibits are types of protective foods caloric values of protective foods and the caloric requirements for eighteen different activities in the home, at work and at play, also shown are values of food containing iron calcium protein and vitamins. Other exhibits expose common food fallacies and show how to get double food value for less money. The nutrition exhibit is based on five rules for a good lunch:

- 1 Your lunch should give you one third of your total daily food
- 2 It should include milk in some form
- 3 It should include whole grain
- 4 It should include some kind of protein as meat eggs, cheese or beans

Specially prepared pamphlets on nutritional problems, including planned diets have been made available to field workers under the new program. Heading the health and nutrition program at Wright Field is Major Zoltan T Wirtzchrist, chief of the civilian Medicine and Industrial Hygiene Section and former instructor at the Cleveland City Hospital, Western Reserve University Medical School.

CLASS OF MEDICAL INSPECTORS

Forty-six medical officers comprising the fourth class of medical inspectors graduated March 13 from a special training course at the Medical Field Service School at Carlisle Barracks, Pennsylvania. Following the exercises, the men left for their new posts. The duties of medical inspectors are to supervise sanitation and other medical preventive measures in army camps. Twenty-two of the forty-six officers had graduated previously from the basic course for officers at the Medical Field Service School. The class included eight majors and thirty-seven captains, all of the Medical Corps, and one captain of the Sanitary Corps. The officers represented twenty-six states. Another class of medical inspectors numbering about fifty officers started on March 22.

ARMY LEASES PART OF MICHIGAN'S LABORATORY FACILITIES

Manufacture by the Army Medical Department of biologic products to be used by the Army, Navy and Coast Guard using facilities of the Michigan Department of Health Laboratories in Lansing, is to begin soon. Leasing two floors of the new Groesbeck serum and vaccine laboratory building now nearing completion, the Army will use its own equipment. The Lansing laboratories of the state department will continue the manufacture of biologic products for state distribution and its other routine services.

NAVY

NEW NAVAL HOSPITAL FACILITIES

The Bureau of Medicine and Surgery of the U S Navy, Washington, D C, announced on March 11 that three new hospital ships had been authorized and on March 5 that a new 1,000 bed naval hospital would be constructed at Pleasanton (Livermore), Calif. The Bureau of Medicine and Surgery at that time expected the early authorization of plans to expand the bed capacity of two other East coast and six West coast naval hospitals, including hospitals at Philadelphia, San Diego, Long Beach, Seattle, Treasure Island, Corona and Santa Margarita.

A new naval hospital with 1,500 beds was formally opened on February 15 in Queens, New York. The hospital had already admitted several hundred patients. The thirty-five wards are of one story wooden barracks type. The commanding officer is Capt L L Pratt, U S N, and the executive officer is Capt B H Adams. The superintendent of nurses is Lieut Comdr Anna Keating, U S N, and the seventy some medical officers on the staff are mostly prominent men in the various specialties. In all there are 71 nurses, 317 members of the navy hospital corps and 235 civilian employees. The hospital is built on one of the fine golf courses on Long Island and is complete in all respects for handling any class of patients. The community in this area and the national organizations have made many donations to the Red Cross unit of the hospital and to the Secretary of the Navy for various forms of equipment.

The U S Navy has opened a new hospital at Key West, Fla, and the Marine Hospital formerly in operation at Key West has been closed. Rear Admiral Luther Sheldon Jr of the Navy Medical Corps, who recently inspected the naval medical facilities in the seventh naval district, reported that he was favorably impressed by the new hospital in Key West.

The Colorado Hotel at Glenwood Springs, Colo, is being prepared as a U S Navy hospital with a 500 bed capacity.

It was announced by representative Lex Green of Florida, February 25, that St Mary's Hospital in West Palm Beach, which was built in 1938, will be taken over by the Navy.

NAVAL DENTAL CORPS REAR ADMIRAL

Recent legislation authorized the temporary appointment of a rear admiral in the dental corps of the U S Navy. A selection board met early in March at the Navy Department and selected for nomination as rear admiral Capt Alexander Gordon Lyle, D C, U S N. Dr Lyle was born at Gloucester, Mass, in 1889, graduated from Baltimore College of Dentistry in 1912 and was commissioned lieutenant (jg) in the Dental Corps of the Navy in 1915. During the first world war Captain Lyle served with the marines in the second division in France and was awarded the Medal of Honor and two Silver Star medals for extraordinary heroism under fire. He served on various ships later and again with the marines in Shanghai, China, and for four years ended in August 1936 was head of the dental department of the U S Naval Hospital, Newport, R I. The following year he completed the course in the Army Industrial College and recently has been head of the dental department of the Naval Air Station, Quonset Point, R I.

WAVES FOR THE HOSPITAL CORPS

A Hospital Corps School for Waves to be established at the Naval Medical Center, Bethesda, Md, has been authorized and construction is expected to start soon. The school will accommodate training classes of 500 students. On March 8 there were 209 Hospital Corps Waves, of whom 97 were on active duty at that time and 122 were undergoing indoctrination at Bethesda and San Diego. The Bureau of Medicine and Surgery expected another 150 on March 22, which would be assigned to indoctrination classes at the naval hospitals at Great Lakes, Ill, New York and Chelsea, Mass. Another group of 150 waves was expected from the Wave School at Cedar Falls, Iowa, on April 5.

NAVAL MEDICAL NEWS LETTER

Bumed News Letter, edited by Capt W W Hall, M C, U S Navy, is issued by the Bureau of Medicine. The letter contains information of importance to all medical officers, especially those isolated by war from the usual sources of medical information. Abstracts of important articles in current medical and scientific periodicals are included. The present microfilm letter, reproduced from material supplied by the Committee on Medical Information of the National Research Council, Division of Medical Sciences, is incorporated with this publication. It is distributed by regular and by V mail to naval medical officers ashore and afloat.

NAVY PERSONALS

Dr Lewis H Wright, head of the department of anesthetics of E R Squibb & Sons, New York, entered the U S Naval Reserve with the rank of lieutenant commander on March 1. Dr Wright joined the anesthetic department of E R Squibb & Sons in 1930 and for several years has been the head of that department.

Air Commodore C P Symonds of the R A F, consultant in neuropsychiatry, visited on March 18 the Bureau of Medicine and Surgery in Washington. Commodore Symonds was in the United States also for the purpose of giving the Dunham Lectures at Harvard University.

Lieut Comdr Clement C Clay of the Navy Medical Corps Reserve has been assigned to the Personnel Division at the Bureau of Medicine and Surgery.

Lieut Gerald J Sullivan, M C, U S Naval Reserve has been assigned to duty at the Naval Dispensary in Washington.

Lieut Comdr Charles Wheatley, M C, U S Navy, retired, has been assigned for duty to the correspondence course section at the Bureau of Medicine and Surgery.

Capt Robert W Wimberly, M C, U S Navy, has reported for duty to the Naval Dispensary, Washington, D C.

Comdr Omar J Brown, M C, U S Navy has been assigned as head of the new section of tropical medicine of the Division of Preventive Medicine of the Bureau of Medicine and Surgery, Washington, D C, and Lieut John F Shrouts, U S Naval Reserve, has been assigned to the section of Venereal Disease Control, replacing Lieut George W Mast, M C, U S Navy, who has been assigned in charge of the section of audiovisual education.

Lieut Comdr W H Schwartz, M C, U S Navy, has been assigned to the Venereal Disease Section in the Bureau of Medicine and Surgery, and Comdr Ladislaus Adamkiewicz, M C, U S Navy, to the research division.

MEDICAL FIELD SETS DONATED TO COAST GUARD

The Illinois Opera Guild Ferry Command and the Drake Hotel Red Cross Unit have presented emergency medical field sets to the U S Coast Guard at Chicago. In forwarding these sets from the Medical and Surgical Relief Committee of America in New York Mrs Huttleston Rogers, executive chairman, writes that the War Shipping Administration has made a request for twenty-four emergency medical field sets to be sent to Casablanca, Dakar, Cape Town, Murmansk, Trinidad and other distant ports. The Anglo American Commission also has requested thirty-six of these units for use in the Caribbean area. The committee requests that physicians and surgeons, particularly, and any other persons who may have scalpels, splinter forceps, probes, grooved directors, scissors and other instruments of this nature send them promptly to the committee's headquarters at 420 Lexington Avenue, New York City. These instruments need not be new, as facilities are available for their repair.

CIVILIAN DEFENSE

BRITISH METHOD OF BLANKETING
A CASUALTY

The British (Wanstead) method of blanketing casualties mentioned in Circular, Medical Series No 20, U S Office of Civilian Defense, is described herewith. Using two blankets as described, there are four thicknesses beneath the patient and two above. The feet are tucked in and kept warm by the use of this technique, and the head is protected against cold. When the blanket fold is completed, it securely fixes the extremities and trunk so that it can be used as a blanket carry, if necessary.

FIGURE 1

FIGURE 2

PREPARING THE STRETCHER

1 Place blanket *A* lengthwise across the stretcher with one side close to the head end of the stretcher, and one end of the blanket having a slightly longer overlap of the stretcher than the other end (fig 1)

2 Fold blanket *B* in thirds lengthwise and place over *A*, the upper edge of this folded blanket being about 15 inches below the upper edge of blanket *A* (fig 2). For very tall persons it is necessary to lay blanket *B* farther down on the stretcher to permit its lower end to extend a sufficient length below the patient's feet so that it may be folded up and around them in the manner to be described.

FIGURE 3

FIGURE 4

3 Open the folds of blanket *B* for about 2 feet at the foot end (fig 2)

WRAPPING A PATIENT

1 Bring the foot of blanket *B* up over the feet, with a small fold between the feet

2 Tuck the two open folds of blanket *B* closely over and around the feet and ankles (fig 3)

3 Turn in upper corners of ends of blanket *A* (fig 3), wrap shorter end of blanket *A* over patient and then the longer end and tuck well in at side (fig 4)

FIGURE 5

FIGURE 6

BLANKET ASSEMBLY FOR TRANSIT

1 Proceed as under 1 and 2 for preparing a stretcher

2 Fold in the two ends of blanket *A* in accordion pleats (fig 5), fold in the foot end of blanket *B*, then roll the blanket and make secure (fig 6). A hot water bottle may be placed in the center of the blanket pack to keep it warm.

TRANSPORTATION FOR CASUALTIES

Transportation for casualties from scenes of disaster to hospitals and for injured persons or other patients removed from casualty receiving hospitals to emergency base hospitals is included in plans for emergency transport service during war disasters described in recent operations letters issued by the Office of Civilian Defense.

Plans for local transportation are entered in the transport officer of the U S Citizens Defense Corps. It is the duty of the transport officer to maintain inventories of local equipment that can be used by the various emergency services of the Citizens Defense Corps, and he is responsible for organization, training and supervision of volunteer drivers units. Such equipment may include passenger cars, station wagons, motorcycles, ambulances and other private vehicles.

Through joint action of the Office of Defense Transportation and the Office of Civilian Defense, local commercial motor vehicles, including taxicabs and trucks of small operators which are now under the jurisdiction of the Office of Defense Transportation, have been released to the transport officer for local service in case of war emergency. He may make use of such vehicles immediately without application to the ODT.

For transport facilities needed outside the local area such as might be required for evacuation of civilians or for transfer of injured persons to emergency base hospitals in other areas, the OCD and the ODT are organizing motor transport units in the larger common contract and private motor carriers of the critical areas of the country. These units will be trained in convoy service. ODT is developing an organization in the critical areas under which its district managers will make contact with the local transport officers to make certain that each community is organized to function under the plan.

Operations Letter No 114, issued March 3, urges cooperative planning between the Citizens Defense Corps and the American Red Cross, the Women's Defense and Ambulance Corps and local or state automobile associations or clubs in order that several agencies may not seek to mobilize the same equipment independently but may do so in cooperation.

IDENTIFICATION OF VEHICLES
IN BLACKOUT

A uniform system of identification of emergency vehicles operating during real or practice air raid alarms was announced by the Office of Civilian Defense in Operations Letter No 111. The primary identifying device is a white pennant measuring 18 inches along each side with a 6 inch basic Civilian Defense insignia, that is the letters CD in red inside a white triangle superimposed on a red circle. The pennant is to be attached to the left front portion of the vehicle. To identify emergency vehicles at night the operations letter prescribes a headlight mask over the right headlamp for use where blackout regulations permit the use of headlights. In coastal dimout areas it should be used in conjunction with dimout equipment. The design of the mask embodies the CD insignia 2 1/2 to 3 inches in diameter in green.

Vehicles entitled to use the emergency identification include (a) vehicle of the armed forces of the United States or of the Allies or other vehicles acting under orders, (b) vehicles of fire departments and governmental police agencies, (c) ambulances and rescue cars and other vehicles converted to such use in emergency services, (d) public utility repair vehicles operating in emergency service and (e) vehicles in emergency service as defined by state civilian defense authorities.

The operations letter recommends that all states adopt the definition of emergency motor vehicles and the methods of identification prescribed. Although many states have already adopted different methods of identifying emergency motor vehicles, it was urged that all states adopt the new devices. A uniform system is important in order that emergency motor vehicles which may be crossing state lines may not face unnecessary interference.

MISCELLANEOUS

AN APPEAL FOR EMERGENCY MEDICAL SUPPLIES

The medical supplies on the French warships now in our ports for repairs are seriously depleted and, at the request of the chief medical officer of the battleship *Richelieu*, the Medical and Surgical Relief Committee of America, with headquarters at 420 Lexington Avenue New York City, has supplied the ship with a complete operating set, including rubber gloves, sutures, needles, antiseptics, thermometers and vitamins.

The chapter of the American Women's Voluntary Services in Winter Park, Fla., has sent to the Medical and Surgical Relief Committee twelve submarine chaser medical kits, three emergency medical field sets and thousands of dressings.

At the request of the British War Relief, the Medical and Surgical Relief Committee of America has sent twelve complete dental units, one hundred extraction forceps and one hundred hypodermic syringes and needles to North Africa.

The Washoe County Medical Society has raised funds to purchase a complete operating set and emergency medical field set for use on board the cruiser *Reno*. The presentation was made at the headquarters of the Medical and Surgical Relief Committee of America, New York City, to a representative of Rear Admiral Melhorn of the Navy Medical Supply Depot in New York.

Many women's clubs throughout the country are conducting special campaigns by placing collection tins and posters in department stores in which the public may donate old scissors, knives, safety pins, bandages, tweezers and fishing tackle for forwarding to the Medical and Surgical Relief Committee of America at 420 Lexington Avenue, New York City, where they will be repaired if necessary and used to equip emergency kits for use on submarine chaser and coast guard patrol boats.

MORE NURSES NEEDED

At a meeting of the directors of the National Nursing Council for War Service in New York, March 19, it was reported that schools of nursing throughout the country admitted 5,000 more students during the current year than they did the year before. However, the total of 49,169 is nearly 6,000 less than the quota which the nursing profession and the government estimated necessary to meet war needs.

"Since 6,000 young women who were needed as nurses are doing something else instead or taking no part in the war effort," said Katherine Faville, chairman of the Council's Committee on Recruitment of Student Nurses "some new element must be added if we are to secure the greatly increased number of new students, 65,000, who should begin nursing educations during the school year that opens June 1. The modest government stipends for student nurses that it suggests should enable more of those qualified to enter nursing and should help meet the competition of high salaried war industry or the various military auxiliary services which offer women a soldier's pay even during training."

The school admissions figures were reported by the Department of Studies of the National League of Nursing Education on the basis of questionnaires sent to the 1,300 state accredited schools of nursing in the country. The admissions for the period June 1, 1942 to June 1, 1943 total 49,169, or 89 per cent of the quota sought. Eight states reached or passed the quotas assigned to them. They are Arkansas, Idaho, Iowa, Minnesota, New Mexico, North Carolina, Oklahoma and West Virginia. Other states which reached 90 per cent or more of their quotas are California, Colorado, Delaware, District of Columbia, Illinois, Indiana, Maine, Massachusetts, Mississippi, Montana, Ohio, Pennsylvania, Rhode Island, Utah and Virginia. The New York State percentage was 86. The Committee on Recruitment of Student Nurses, now launching a heightened spring campaign will study the areas where success was achieved in comparison with states where fewer girls entered nursing, to seek light on reasons, and to devise better methods.

HEALTH UNDER HITLER

It is reported from Presov, according to *Grenzboten* Bratislava, of Nov 24, 1942, that all persons between 2 and 80 were compulsorily inoculated against typhus. Simultaneously the inoculation of all dogs against rabies was decreed.

Donauzeitung, Belgrade, of Nov 12, 1942 reports that the Rumanian cabinet has resolved to set up a commission to purchase medical supplies, bandages and medical instruments. This purchasing commission has been instructed to purchase the necessary materials for the social central insurance office from Germany and Italy.

DNB of January 7 states that the systematic care for the health of young persons has now been enriched by a work unique in various respects and of fundamental significance for the future. It is the "Principles Laid Down by the Reich Health Leader and Reich Youth Leader on Health Services for Youth," which the reich minister of the interior has made obligatory. For the first time a large scale scheme which comprises an entire nation and makes use of all means at the disposal of modern science has been devised providing for periodic free medical examinations for all boys and girls from their sixth to their eighteenth year as a joint task of the party and the state. During the war this health scheme will comprise only certain age groups, while it is to be put into practice fully after the war. In his introduction, Conti states that care for the health of youths is the core of the entire health service. It constitutes, as Reich Youth Leader Axmann points out in his preface, one of the foundations of the work of the Hitler Youth and its promotion should be the main task of every doctor and youth leader. A sufficient number of doctors for juveniles will have to carry out the medical service according to the "Principles." The task of the official (staatlich) doctor for juveniles—a profession now coming into existence—is one of the highest responsibility toward the community. To start with, a series of five examinations is envisaged for peacetime. The juveniles are to be examined at the ages of about 6, 10, 14, 15 and 18. To this must be added five to six "medical roll calls" for children up to the age of 14 and, furthermore, yearly "dental roll calls." The examinations are based on the youth health record sheet, which is uniform throughout the reich; the latter is covered by the doctor's obligation for secrecy and every child from his sixth to his eighteenth year will have one.

The wartime reich physician of the Hitler Youth, Ministerialrat Dr. Liebenow, who compiled the "Principles" in collaboration with competent authorities, calls this series of examinations the core of the Youth Health Service. These examinations which make use of x-ray photography too, deal with the juvenile's general constitution, environment, internal organs, sight and hearing, muscles, skeleton, wrong carriage, complexion—in short, with everything which is significant for a general medical supervision. The examinations pursue the following aims: exact medical reports which take into consideration hereditary factors, assessing physical capacities, making available measures necessary to improve the state of health, entries into fitness certificates in which the points that call for consideration are stated as far as necessary, and the supply of material for the health statistics concerning the juvenile population. In the case of the 10 year old child it will be possible to include at the same time a statement on the child's fitness to join the "Jungvolk" or the "Jungmadelbund," or for the hauptschule, while with regard to the 14 year old child his fitness for work will be stated. In the case of the 15 year old child attention will be paid to the influence of the first year of employment on his working capacity and development. It is left open to the parents to give written information regarding the wishes or ailments of the child. The "medical roll calls" are intended to fill the gaps between the series of examinations as far as is possible. The doctor for juveniles is expected to discern health defects at an early stage and give helpful advice for the child's development, while any actual medical treatment which may become necessary is to be left to the doctor chosen by the family.

ORGANIZATION SECTION

OFFICIAL NOTES

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD

FEB 18-19, 1943

Careful consideration was given to the business of the Association at the annual meeting of the Board of Trustees, which was held in the headquarters office on February 18-19, preceded by a full day meeting of the Executive Committee

FURTHER TRAINING OF PHYSICIANS BOTH IN AND OUT OF THE ARMED FORCES

The Board voted to sponsor plans for the further training of physicians both in and out of the armed forces in cooperation with the American College of Physicians and the American College of Surgeons. It elected Dr Edward L. Bortz of Philadelphia to act as its representative and made an appropriation to aid in putting the plan into effect.

NATIONAL CONFERENCE ON PLANNING FOR WAR AND POSTWAR MEDICAL SERVICES

The Board also voted to cooperate with other organizations in the medical and allied fields in sponsoring a conference on planning for war and postwar medical services to be held in New York on March 15.

POSTWAR PLANS FOR MEDICAL CARE

Drs Roger I. Lee (Chairman), James E. Paulin, Fred W. Rankin and H. H. Shoulders were appointed a committee on postwar plans for medical care with authority to enlarge the committee to eight or more persons. This committee will cooperate with similar committees which will be appointed by the American College of Physicians and the American College of Surgeons.

DINNER FOR HOUSE OF DELEGATES

The Executive Committee was authorized to arrange for a dinner for the House of Delegates on Monday evening June 7, and for a meeting immediately thereafter to which will be invited as guest speakers persons who can inform the House on questions of current interest, and if, because of war restrictions it is impossible to arrange for a dinner, to plan simply for the evening meeting with guest speakers.

RECORDING OF BROADCASTS FOR THE USE OF COUNTY SOCIETIES

Authorization was given by the Board for the recording of some of the interview programs over WLS under the title "Before the Doctor Comes," in which Dr W. W. Bauer is cooperating, and for procuring copies of each recording with a view to furnishing these to county medical societies or local stations which may at the present time have difficulty in securing persons to broadcast.

APPROPRIATIONS

Appropriations were made for the conduct of the work of the various councils, bureaus and departments in the headquarters office for regularly held conferences, for the committees on Scientific and Therapeutic Research and for some special research projects.

COMMITTEE ON CONSERVATION OF VISION

The Committee on Conservation of Vision and Prevention of Blindness that was appointed by the Board of Trustees in 1940 in accordance with a resolution from the Section on Ophthalmology adopted by the House of Delegates, which has failed to function, was discontinued by the Board and a new Committee on Conservation of Vision was appointed consisting of Dr Lawrence T. Post, St. Louis, Dr Conrad Berens, New York,

Dr J. V. Cassidy, South Bend, Ind., Dr E. C. Ellett, Memphis, Tenn., Dr Harry S. Graddie, Chicago, and Dr R. S. Irvine, San Francisco.

INVESTMENTS

Consideration was given to the matter of investing some of the funds of the Association, and a selection of eight bonds was made to add to the Association's portfolio.

APPOINTMENTS

The following appointments were made to fill vacancies on various councils, committees and editorial boards (the appointee succeeded himself unless it is otherwise stated).

American Journal of Diseases of Children Dr Oscar M. Schloss, Dr A. A. Weech of Cincinnati to succeed Dr A. Gracie Mitchell (deceased), and Dr James L. Wilson of Detroit to succeed Dr Horton R. Casparis (deceased). *Archives of Dermatology and Syphilology* Dr C. Guy Lane. *Archives of Ophthalmology* Dr David G. Cogan. *Archives of Pathology* Dr James L. Wang. *Archives of Surgery* Dr Arthur W. Allen and Dr Albert J. Scholl of Los Angeles to succeed Dr Wallace I. Terry (resigned). *Archives of Internal Medicine* Dr A. C. Gilbert. *Archives of Otolaryngology* Dr Ernest M. Seydell of Wichita, Kan., to succeed Dr W. P. Wherry (deceased). *Archives of Neurology and Psychiatry* Dr Wilder Penfield, and Dr Charles D. Aring of Cincinnati to succeed Dr S. W. Ranson (deceased). Council on Physical Therapy Dr John S. Coulter, Dr W. W. Cobbentz and Dr W. E. Garrey. Council on Foods and Nutrition Dr George R. Cowgill and Dr Lydia J. Roberts. Council on Pharmacy and Chemistry Dr H. A. Cole, Dr C. S. Keefer and Dr Stuart Mudd. Council on Industrial Health, Dr Everett D. Bristol. Dr Stanley J. Sieger and Mr Philip Drinker. Committee on Scientific Research, Dr John J. Morton. Committee to Study Air Conditioning, Dr Abram L. Brinck of New York as an additional member. Joint Committee on Health Problems in Education of National Education Association and American Medical Association, Dr A. J. Chesley. American Documentation Institute, Dr Ludwig Hektorn, Chicago. Foundation for the Study of Cycles, Dr Kenneth Mayne. Special Committee on Hospital Libraries, Dr William G. Hibbs, Chicago.

DISCONTINUATION OF TRANSACTIONS OF SECTION ON LARYNGOLOGY, OTITIS AND RHINOLOGY

Authorization was given for the discontinuation of the Transactions of the Section on Laryngology, Otolaryngology and Rhinology unless the number of orders is increased sufficiently to indicate that specialists in this field are interested in having the Transactions in book form.

UNITED STATES OF AMERICA AND AMERICAN MEDICAL ASSOCIATION

The Board unanimously adopted the following statement regarding the decision of the Supreme Court of the United States in the case of the *United States of America v. the American Medical Association and the Medical Society of the District of Columbia*.

The decision of the Supreme Court in regard to the case involving the Medical Society of the District of Columbia and the American Medical Association was announced January 18 and was published in *THE JOURNAL* on January 23. On the advice of Counsel a check for \$2,500 has been sent to pay the fine assessed by the District Court against the American Medical Association. Following further advice of Counsel analysis or interpretation of this decision has not been made.

The policies of the American Medical Association in the standardization of medical education, hospitals or other aspects of medical care are established by the House of Delegates. In the conduct of its defense in this case the Board acted on the authority of the House of Delegates in each instance given unanimously.

Many other subjects were discussed some of which will receive further consideration in the future.

MEETING OF THE COUNCIL ON INDUSTRIAL HEALTH

The eleventh meeting of the Council on Industrial Health was held on January 10 at the Palmer House in Chicago. Council members in attendance were Stanley J. Seeger, chairman, Harvey Bartle, Leverett D. Bristol, Warren F. Draper, Philip Drinker, Leroy U. Gardner, Raymond Hussey, Anthony I. Lanza, Robert T. Legge, Clarence D. Selby, William D. Stroud and Carl M. Peterson, secretary.

REPORT OF THE COMMITTEE ON RULES

The Committee on Rules presented a report, rearranging the tenure of service of members of the Council on Industrial Health at four years, so staggered that three appointments expire each year.

REPORT OF THE COMMITTEE ON NOMENCLATURE

After extended discussion the Council resolved (1) to defer publication of the dictionary on industrial health until Dr. Henry Kessler can resume active direction, (2) that the Council discharge its current obligations for services rendered in this direction, (3) that the material remain in the chairman's hands or such additions and revisions as may profitably be added from time to time and (4) that a small additional appropriation be requested as recompense for additional editorial and clerical services.

REPORT OF COMMITTEE ON PROFESSIONAL RELATIONSHIPS

Since early February, forty-two state medical societies have been visited, eighteen of them two or more times. Seven state medical societies appointed committees on industrial health during the year, making a total of forty-five. Loss of committee members to military service and for other reasons required reorganization of the established committees in eight states.

Field procedure in the various states depended on the amount of previous activity and the needs of the area. In almost every state the chairman and members of the committee on industrial health, secretary and other officers of the state medical society, and the bureau of industrial hygiene were visited. Where indicated and possible, the deans of medical schools, state health commissioners and industrial organizations were contacted. Emphasis was placed on better health in relation to war production, the need for better medical organization and leadership, education of the medical profession, industry and other interested agencies, and active cooperation with state procurement and assignment agencies in solving medical problems in industry.

Similar activities are planned for the coming year assisted, as soon as possible, by additional personnel already authorized by the Board of Trustees. It is planned to stimulate reorganization of those state committees which have not been active and to encourage broader and more comprehensive programs in those which have shown progress.

The advisory committees representing the sections in the Scientific Assembly of the American Medical Association are of great assistance to the Council in its educational and organizational activities. This phase of the program will be pressed during the months ahead.

Considerable discussion occurred about the status of the Council in relation to the War Participation Committee of the A. M. A. respecting (1) local organization for industrial health service in a small plant and (2) a program of training and procurement of physicians for industry.

Principal concern referred to recent arrangements under which the U. S. Public Health Service and the Procurement and Assignment Service will jointly undertake studies of war industry and extracantonment areas from which shortages of medical and allied professional personnel are reported. As reported these studies shall be made jointly by the Procurement and

Assignment Service and representatives of the U. S. Public Health Service. The state medical society and the state health department will each be invited also to designate a representative to participate in such studies.

In the discussion of this important statement of policy, the Council received instruction on two main points: (1) whether this language superseded past resolutions of the Procurement and Assignment Service which called on the Council on Industrial Health and the state medical society committees on industrial health to undertake certain functions in respect to procurement training and assignment of physicians for industry, and (2) whether this statement coincided with sentiment developed through field activity of the Council that the resources of county and state medical societies had not been fully explored as a means for bringing willing physicians and industrial opportunities together.

Reassurance was received that such facilities as the Council and its cooperating state agencies could bring to bear on this troublesome problem would be welcome. It was further suggested that the Central Board of Procurement and Assignment should be asked to reinform its regional and state chairmen to this effect.

REPORT OF COMMITTEE ON EDUCATION AND PUBLICATIONS

Evidence was presented indicating that additional progress had been made in the development of courses of instruction in medical schools. A syllabus for a course in industrial health recently submitted to all approved medical colleges in the United States and Canada was ordered to be revised according to new advances made in the field.

The report also reviewed progress in postgraduate industrial medical teaching ranging from refresher courses to intensive teaching. Attention was called to the fact that there are at the present time no training appointments in the industrial field offering acceptable internship or residency experience. It was thought desirable to approach the Council on Medical Education and Hospitals for advice and encouragement along these lines.

The desirability of preparation of local health officers for industrial hygiene was reaffirmed as a means toward better acquaintance with industrial health problems by the profession at large. Particular mention was made of the difficulties of establishing a certification program in the industrial health field and the present status of that program.

The Council noted with interest the progress made toward the development of a joint program with the Council on Pharmacy and Chemistry with a view to preparing and publishing an industrial medical formulary. Steps required to appoint a suitable committee representing the Council on Industrial Health and the presentation of a proper request to the Council on Pharmacy and Chemistry in order that a similar subcommittee be set up in that body were approved.

The secretary was also instructed to obtain advice and active cooperation from the Bureau of Health Education of the A. M. A. in respect to a program of health education for labor organizations.

REPORT OF COMMITTEE ON PHYSICAL EXAMINATIONS

In consideration of the importance of industrial physical examinations the committee was asked to continue its consideration of the subject with a view toward publication of a report at the earliest possible time.

REPORT OF COMMITTEE ON OCCUPATIONAL DISEASE REPORTING

The Council registered its understanding that occupational disease reporting included absenteeism studies and expressed the hope that recommendations may be developed to improve medicine's contribution in this field.

REPORT OF COMMITTEE ON WORKMEN'S COMPENSATION

A program for coordination of effort between the Council on Industrial Health, the Bureau of Legal Medicine and Legislation and the Council on Physical Therapy in the related fields of workmen's compensation and rehabilitation was regarded as a definite step forward.

The preparation of reviews concerning best prevailing medical opinion on medical subjects having some legal connotation was again proposed. It is the intention of the committee to proceed along these lines at the earliest opportunity. In this connection again the necessity for close cooperation with the Bureau of Legal Medicine and Legislation was emphasized.

The committee also recommended as a possible development for the future, a special conference to discuss the whole problem of workmen's compensation with regard to improved medical relationships and many other details of administration. Augmentation of the present personnel of the Committee on Workmen's Compensation to include experts in the fields of medicine, management, insurance, labor and others was looked on as urgently necessary.

It was pointed out that the National Tuberculosis Association is attempting to collaborate with the Council through the appointment of editorial writers to introduce the subject of industrial medicine in monthly publications. In addition, the Trudeau Society has appointed a Committee on Industrial Tuberculosis.

REPORT OF COMMITTEE ON RESEARCH

The chairman reported several conferences with the chairman of the Committee on Occupational Pathology regarding the development of a registry of lung tissue from persons subjected to various industrial exposures.

The Committee on Research was instructed to interest itself in the possibility of clinical investigation through the cooperating committees in the sections of the A. M. A. and the availability of funds within the Association itself for the carrying on of such research.

REPORT OF COMMITTEE ON AVIATION MEDICINE

The Council discharged its Committee on Aviation Medicine.

INDUSTRIAL NURSING

The Council ordered the preparation of an Outline of Procedure for Nurses in Industry. It was recommended that in the preparation of this material special care be taken not to duplicate activity taking place in other organizations. In this connection consideration was given data submitted by the Committee to Study the Duties of Nurses in Industry of the Nursing Section of the American Public Health Association.

NUTRITION IN INDUSTRY

The first meeting of the Joint Committee on Nutrition in Industry, made up of representatives from the Council on Industrial Health and the Council on Foods and Nutrition was described, together with plans for a symposium on nutrition in industry to be sponsored by this committee at the fifth Annual Congress on Industrial Health.

INDUSTRIAL MEDICAL SERVICE PLANS

As soon as conditions warrant, information will be collected from likely sources on industrial medical service plans.

LABOR ORGANIZATIONS AND INDUSTRIAL HEALTH

The general impression was that there should be closer contact with labor organizations and that some effort should be made to enlist their cooperation, both in the maintenance of industrial health services within the plant and in general programs of health education covering nonoccupational disability.

REHABILITATION COUNCIL

The attention of the Council was directed to the formation of a Rehabilitation Council representing thirty-eight national agencies interested in the vocational and reconstructive phases of rehabilitation. Because of the Council's interest in the sub-

ject, and because the Council on Physical Therapy is represented on the Rehabilitation Council, and since furthermore, the question of rehabilitation will be of unusual importance during the present legislative year it was decided to create a liaison committee with the Council on Physical Therapy as a means of maintaining close contact with activities in the rehabilitation field and for the purpose of formulating reports and specific recommendations.

THE U. S. MARITIME COMMISSION

The U. S. Maritime Commission wishes to enlist the help of the Council on Industrial Health to instruct physicians in the neighborhood of shipyards about special care required for workers who suffer from exposures which may not manifest themselves until after the men have left work.

THE U. S. CHAMBER OF COMMERCE

Plans for an advisory health council in the Chamber of Commerce of the United States were described with particular reference to a subcommittee on industrial health and the possibilities for integrated educational programs for employers and physicians.

Dr. Stanley I. Seeger and Dr. Raymond Hussey were unanimously reelected as chairman and vice chairman respectively.

Names were submitted as nominations for expired terms in accordance with recently revised rules of the Council.

The next meeting of the Council was set tentatively for Sunday, June 6 in Chicago, just preceding the meetings of the House of Delegates.

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 5 p. m. Eastern War Time (4 p. m. Central War Time, 3 p. m. Mountain War Time, 2 p. m. Pacific War Time). An exception is the Chicago area where the broadcasts are heard by transcription at 10-30 p. m. Saturdays over Station WMAQ.

The titles and guest speakers for the next four programs are as follows:

- April 17 Stratosphere Flight
Speaker: Brig. Gen. David A. W. Grant, Air Surgeon, United States Army
- April 24 Sharp Lanes
Speaker: Lieut. Col. Harold C. Lueth, Liaison Officer, Surgeon General's Office, United States Army
- May 1 Jungle Death
Speaker: Brig. Gen. C. C. Hillman, Chief of the Professional Services Office of the Surgeon General, United States Army
- May 8 'Drugs March to War'
Speaker: Dr. Austin I. Smith, Secretary, Council on Pharmacy and Chemistry

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled "Before the Doctor Comes" will be on the air every Thursday morning at 9-45 up to and including May 27. Mrs. June Merrill will interview Dr. W. W. Bauer, Director of the Bureau of Health Education, Dr. Edwin P. Jordan, Assistant Editor of THE JOURNAL or Dr. Austin I. Smith, Secretary of the Council on Pharmacy and Chemistry on common home health problems. The titles for the next four programs are:

- April 15 The Listless or Irritable Child
(Jordan)
- April 22 What to Do About Bad Bumps
(Bauer)
- April 29 What to Do About Bleeding
(Bauer)
- May 6 What to Do About Foreign Bodies in Nose, Ear, Throat or Eyes
(Smith)

MEDICAL ECONOMIC ABSTRACTS

RETURN AND PAYMENT OF VICTORY
TAX BY EMPLOYER

Physicians who have withheld the victory tax from wages paid employees must make a return and transmit that tax to the collector of internal revenue having jurisdiction on or before April 30, using form V-1 Return of Victory Tax Withheld. This form may be obtained from the collector's office and must be signed and sworn to by the employer. The duplicates of receipts given employees (form V-2) need not be forwarded to the collector at this time, they should be retained by the employer until the final return is made for the year, on or before Jan 31, 1944. In view of the severe penalties that may attach in event an employer neglects to transmit the withheld victory tax on or before the required date, physicians should transmit promptly the tax withheld during the months of January, February and March of this year.

MEDICAL CARE FOR WIVES AND
CHILDREN OF ENLISTED MEN

The President on March 18 approved a deficiency appropriation bill making available to the Children's Bureau \$1,200,000 for grants to states to provide medical nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the fourth, fifth, sixth and seventh grades. This appropriation will permit the continuation until June 30 of a program initiated last year and financed to date by federal allotments totaling \$390,177 set aside from the regular appropriation authorized for maternal and child health services under part I, title V, of the Social Security Act. No more funds were available from that source hence the appeal to Congress for this deficiency appropriation. Legislation is pending in Congress to authorize additional funds so that the program may extend beyond the present fiscal year.

Regulations have now been promulgated by the Department of Labor, dated March 26, for the allotment of the \$1,200,000 to the several states.¹ These regulations provide that the sums paid to the states for emergency medical and infant care shall be used exclusively for medical, nursing and hospital maternity and infant care for wives and infants of enlisted men in the armed forces of the United States of the fourth, fifth, sixth or seventh grades, for whom similar care is not readily available from the medical or hospital facilities of the Army or Navy or from facilities provided by or through official state or local health agencies. The Secretary of Labor will allot to each state submitting a plan approved by the chief of the Children's Bureau a sum based on the estimated number of applications for care during the period covered by the plan and the esti-

mated cost of providing such care. A state plan must, among other things provide that the cost of administration in the state will be met from funds other than the sums allotted for emergency maternity and infant care that emergency maternity and infant care will be authorized under the plan as requested by or in behalf of any wife or infant of an enlisted man in the indicated grades, irrespective of legal residence, when similar care is not otherwise readily available and must provide for cooperation with medical nursing and welfare groups and organizations.

The chief of the Children's Bureau Katharine F. Lenroot appeared before a subcommittee of the House Committee on Appropriations, February 11 in support of the request for this additional appropriation. She pointed out that plans at that time had been approved and programs were going forward in twenty-seven states and that similar programs would be developed in at least sixteen additional states if more funds become available. A table was supplied to the subcommittee indicating that for the period August 1942 to February 1943 a total of 2,840 obstetric cases had been authorized for medical and hospital care in twenty-one states. Experience obtained during the then five past months Miss Lenroot said, showed that the demand for services was very great and that the sums available had not been sufficient to enable some states to accept all the cases for which application had been made. While the exact data on waiting lists were not available from all the states, it was known that one state had in December 1942 a waiting list of 300 and another of 400. Still another state was receiving applications at the rate of 12 a day and estimated an increase to 20 a day. At the request of the chairman of the subcommittee Miss Lenroot inserted in the record the requirements exacted of a state board of health as a condition to cooperation on the part of the Children's Bureau in connection with this program. The following was submitted in compliance with that request:

The Children's Bureau has informed the state health departments that the state plans for obstetric or pediatric medical and hospital care for women or children when the father is an enlisted man of the fourth, fifth, sixth or seventh grades in the Army of the United States, the United States Navy, the Marine Corps or the Coast Guard should provide efficient methods of administration or the plan by the state health agency including acceptance of cases regardless of legal residence, the establishment of methods of authorization for medical or hospital care, methods of referral of cases to public health nursing and social services as needed, the establishment of fixed rates of reimbursement for services rendered under the plan, safeguards of the quality of medical and hospital care.

Grants in aid will be made quarterly to the states on the basis of (1) current experience in each state with respect to the number of birth certificates issued showing the father to be in military service, (2) the cost of service per case within limits based on average cost of care for the area and (3) the number of authorizations per month.

It is expected that the administration of these funds will be in accordance with the conditions laid down in the Social Security Act, title V, part I, section 503 (a) items (2) through (6) inclusive under which the existing services comparable to those to be provided under this proposed appropriation are now administered.

1 8 Fed. Reg. 3859 March 30 1943

WOMAN'S AUXILIARY

WOMAN'S AUXILIARY TO THE AMERICAN
MEDICAL ASSOCIATION

Twenty-First Annual Meeting, June 7-9, 1943
Drake Hotel, Chicago

A most cordial invitation is extended to all Auxiliary members and the wives of physicians attending the American Medical Association meeting to attend the sessions of the twenty-first Annual Meeting of the Woman's Auxiliary to the American Medical Association. Mrs. Rollo K. Packard is chairman of the Chicago Committee.

Headquarters will be in the Grand Ballroom of the Drake Hotel, where all meetings will be held. Please register early and obtain your badge and program. Tickets may be purchased at the registration desk.

All meetings will convene at the time scheduled. Please be prompt.

Registration, in the French Room Foyer

Sunday 2 to 4 p. m.
Monday, 8 30 a. m. to 4 p. m.
Tuesday, 8 30 a. m. to 4 p. m.

Preconvention Meetings

SUNDAY, JUNE 6

3 p. m. Nominating Committee meeting, Parlor H (east mezzanine), chairman Mrs. Robert E. Fitzgerald.

7 p. m. Finance Committee meeting, chairman Mrs. Harold F. Wahlquist.

PROGRAM

MONDAY, JUNE 7

9 a. m. Meeting of the Board of Directors, Parlors F-G (east mezzanine), Mrs. Frank N. Haggard presiding.

12 30 p. m. Luncheon in honor of the past presidents of the Woman's Auxiliary to the American Medical Association. Gold

Coast Room Tickets \$2.25 (subject to market conditions and food administration regulations) Guest speaker Dr. Frank P. Hammond, chairman of the Advisory Committee of the Women's Auxiliary to the Illinois State Medical Society Subject Doctors' Wives—Medicine's Closest Ally

Convention Meetings

MONDAY, JUNE 7

2 p. m. Opening meeting of the House of Delegates of the Women's Auxiliary to the American Medical Association, Grand Ballroom (lobby floor east), Mrs. Frank N. Haggard, President

Invocation Rev. Harrison Ray Anderson, Fourth Presbyterian Church, Chicago

Address of Welcome Hon. Edward J. Kelly, Mayor of Chicago

Tribute to Deceased Members

Introduction of Mrs. Rollo K. Packard, chairman of the Chicago Committee

Presentation of the President-Elect, Mrs. Eben J. Carter

Minutes of the Twentieth Annual Meeting Mrs. Carlton F. Potter, Secretary

Roll Call Mrs. Carlton F. Potter

Convention Rules of Order Mrs. Silas S. Smith

Credentials and Registration Mrs. Arthur I. Edison

President's Message Mrs. Frank N. Haggard

Reports of Officers

Recording Secretary Mrs. Carlton F. Potter

Corresponding Secretary Mrs. Scott C. Applewhite

Treasurer, Mrs. David W. Thomas

Auditor to be read by the recording secretary

Reports of Directors

Mrs. R. E. Mosiman

Mrs. James P. Simonds

Mrs. John Baron Farley

Mrs. W. K. West

Mrs. Frank I. Davis

Mrs. David B. Altmann

Mrs. William J. Butler

TUESDAY, JUNE 8

9 a. m. General session of the Women's Auxiliary to the American Medical Association, Grand Ballroom, Mrs. Frank N. Haggard presiding

Minutes Mrs. Carlton F. Potter

Credentials and Registration Mrs. Arthur I. Edison

Resolutions Mrs. James P. Simonds

Reports of Chairmen of Standing Committees

Finance, Mrs. Harold F. Wahlquist

Hygiene, Mrs. George R. Dillinger

Legislation, Mrs. Luther H. Kice

Organization, Mrs. T. Mitchell Burns

Press and Publicity, Mrs. George H. Howell

Program, Mrs. William Hibbits

Public Relations, Mrs. Frank P. Dwyer

Revisions, Mrs. Eustace A. Allen

Report of Historian, Mrs. John J. Ryan

Report of Bulletin Circulation and Central Office, Miss Margaret Wolfe

Reports of state presidents

12:30 p. m. Luncheon in honor of Mrs. Frank N. Haggard, President, Gold Coast Room Tickets \$2.25 (subject to market conditions and food administration regulations)

Guest Speakers Brig. Gen. Fred Rankin, President American Medical Association; Dr. James I. Paullin, President-Flect American Medical Association; Dr. Morris Fishbein, Editor THE JOURNAL AND NATURE

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—S. 400 has passed the Senate, a bill to reorganize the United States Public Health Service. The amendment declaring osteopaths eligible for appointment as reserve officers in the service was retained in the bill as passed by the Senate.

Bills Introduced—S. 927 introduced by Senator Thomas Oklahoma provides that the amount of disability compensation or disability allowance payable to any veteran under the World War Veterans' Act, 1924, as amended and supplemented shall not be reduced if such veteran (1) has attained or hereafter attains the age of 40, and (2) has received for a total period of five years or more disability compensation or a disability allowance for total permanent disability resulting from tuberculosis. H. R. 2308, introduced by Representative Lesinski, Michigan provides vocational rehabilitation for members of the Regular Establishment after termination of hostilities in the present war. H. R. 2326, introduced by Representative Bolton Ohio, provides that for the purpose of assuring a supply of nurses for the armed forces, governmental and civilian hospitals, health agencies, and war industries there will be authorized such annual appropriations as may be necessary. Such sums will be used in making payments to schools of nursing or other institutions which have submitted and had approved by the Surgeon General of the United States Public Health Service plans for nurses training. A plan for training of nurses may be limited to student nurse training or to postgraduate or refresher-nursing courses or may include both. The plans to be approved must provide, among other things, that the institution will pay student nurses a stipend at not less than the following monthly rates: \$15 for the first nine months of study, \$20 for the following fifteen to twenty-one months of combined study and practice depending on the curriculum of the institution. A plan must provide too that the institution will either afford student nurses under the plan an opportunity to complete their course of training until graduation and will pay such student nurse a stipend at a monthly rate of not less than \$30 for

the period following the period of combined study and practice prior to graduation or will transfer such student after completion of the period of combined study and practice prior to graduation, for training in some other institution. H. R. 2330 introduced by Representative Sonners New York, would authorize an appropriation of \$1,500,000 to construct in the borough of Brooklyn, city of New York a modern, fireproof general medical and surgical hospital and domiciliary facility for the care and treatment of veterans with a capacity of at least 500 beds.

STATE MEDICAL LEGISLATION

Kansas

Bills Enacted—S. Res. 25 was adopted March 12. It directs the legislative council to study the advisability and necessity for the inclusion in the benefits of the workmen's compensation act of workmen suffering from occupational diseases and further directs that the council make a report of its study at the next regular session of the legislature together with such recommendations as it may see fit to adopt. H. 332 was approved March 22. It requires every physician to take or cause to be taken a sample of blood of any woman whom he diagnoses as being pregnant such sample to be taken within fourteen days after the diagnosis is made.

Maine

Bill Introduced—H. 632 to amend the prerogative examination law, was amended in the house by eliminating therefrom the provision authorizing a doctor of the armed forces of the United States to execute the required certificate.

Bill Enacted—S. 304 has become chapter 155 of the Public Laws of 1943. It amends the osteopathic practice act by authorizing approved osteopathic schools to give a course of instruction for a total of thirty-six months within a three to four year period when such school has adopted compressed or accelerated courses as a war emergency measure.

Maryland

Bill Introduced—H 644 proposes certain regulations concerning advertising by persons practicing medicine and surgery

Michigan

Bills Enacted—S 113 has become Public Act No 33 of the Acts of 1943. It amends the medical practice act by authorizing the Michigan state board of registration in medicine to suspend in whole or in part the educational requirements prescribed by the act at any time during the state of war now existing between the United States and various other nations. S 192 has become Public Act No 44 of the Acts of 1943. It amends the osteopathic law by authorizing the Michigan state board of osteopathic registration and examination to modify, by order, the educational requirements prescribed by the present act, during the present emergency.

Minnesota

Bill Introduced—S 1079 proposes the creation of a committee at least two members of which shall be doctors of medicine appointed by the council of the Minnesota State Medical Association, for the purpose of establishing standards and prescribing scientifically approved methods to secure the selection of children with an impaired sense of hearing and to institute an educational program for the prompt medical correction thereof.

Missouri

Bills Introduced—S 79 proposes a new law to be known as the Missouri Food, Drug and Cosmetic Act. Among other things, it proposes that a drug shall be deemed misbranded if it is sold at retail and contains any quantity of aminopyrine, barbituric acid, cinchophen, dimetiphenol, sulfanilamide, or their derivatives or any other drug which has been found by the board to be dangerous to health when used in the dosage or with the frequency or duration prescribed, recommended or suggested in the label thereof, unless such drug is sold on a written prescription signed by a licensed physician, dentist or veterinarian and its label bears the name and place of business of the seller, the serial number and date of such prescription, and the name of such physician, dentist or veterinarian. When sold on such written prescription such drug shall be exempt from the other provisions of the proposal. S 98 proposes the creation of a state board of examiners in the basic sciences to examine, in the subjects of anatomy, physiology, chemistry, bacteriology and pathology, all applicants for a license to practice any form of the healing art.

Nebraska

Bills Enacted—Bill No 40 was approved March 27. It requires each applicant for a marriage license to present a certificate signed by a duly qualified physician licensed to practice medicine and surgery in any state or United States territory, or any other person authorized by the laws of Nebraska to make such certificate, certifying that the applicant is not infected with syphilis in a communicable stage. Bill No 41 was approved, March 27. It requires every physician, or other person authorized by law to practice obstetrics, attending a pregnant woman to take a sample of blood of such woman at the first examination and submit such sample to an approved laboratory for a standard serologic test for syphilis.

Nevada

Bill Enacted—A 141 was approved March 20. It authorizes the board of medical examiners to grant qualified physicians a temporary license to practice medicine, surgery or obstetrics in any particularly specified part of the state for and during the period of time limited by the license. The law further authorizes the board of medical examiners from time to time to restrict, enlarge or change the territorial limits stated in such temporary license.

New Jersey

Bills Introduced—S 95 proposes the establishment of an elective system of compensation for silicosis and asbestosis. S 143 proposes to authorize the state department of health to

require a person suspected of suffering from a communicable disease, or suspected of being a carrier of such disease, to submit to a medical examination made by a physician or laboratory selected by the state department of health or the local board of health. S 158 proposes the establishment within the department of institutions and agencies of a division whose duty it shall be to study the causes, mortality rate, treatment, prevention and cure of cancer and allied diseases and proposes to authorize the department to make a careful study of the cancer situation in the state, organize cancer clinics at various points throughout the state, conduct a program of public education regarding the care, treatment and prevention of cancer and erect and maintain a state hospital wherein cancer patients may be received for care and treatment.

Bill Enacted—A 93 has become chapter 17 of the Laws of 1943. It amends the medical practice act by granting an extension of two years within which a licensee must furnish proof of his actually having become a citizen.

New York

Bills Passed—A 335 passed the assembly on March 16 and the senate on March 17. It proposes to authorize the state commissioner of health to employ necessary medical and health personnel for rendering services in areas designated by the governor as being emergency health and sanitation areas by virtue of an inadequacy of medical facilities or personnel therein. Compensation to such employed medical personnel may be paid by the state department of health. A 1923 passed the assembly on March 24 and the Senate on March 26. To amend the mental hygiene law, it proposes to eliminate the existing requirement that the head of the department be a reputable physician with at least ten years experience in the actual practice of his profession and at least five years actual experience in the care and treatment of persons afflicted with mental disease in an institution for their care and treatment. It then proposes to provide for the appointment of a medical director who shall be a reputable physician, a graduate of an incorporated medical college, with at least ten years experience in the actual practice of his profession and at least five years actual experience in the care and treatment of persons afflicted with mental disease in an institution for their care and treatment. The duties of the proposed medical director would be to advise with the commissioner on all matters affecting medical policy within the department, have direct charge and control, under the general departmental direction of the commissioner, of medical administration, care and treatment and of medical and nursing personnel and perform such other duties in the place and stead of the commissioner as may lawfully be assigned to him.

North Carolina

Bills Enacted—S 211 was ratified March 6. It amends the law relating to the incorporation of nonprofit hospital service corporations so as to authorize the operation of nonprofit medical service plans as well. The term 'hospital service plan' is defined as including the contracting for hospital care, laboratory facilities, x-ray facilities, drugs, appliances, anesthesia, nursing care, operating and obstetric equipment, accommodations and any other services authorized or permitted to be furnished by a hospital under the laws of North Carolina and approved by the North Carolina Hospital Association or the American Medical Association. The term medical service plan is defined as including the contracting for medical, obstetric, surgical and any other professional services authorized to be furnished by a duly licensed physician. S 254 was ratified, March 10. It authorizes the creation of a Hospital Authority to engage in hospital construction, maintenance and operation. H 174 was approved February 15. It amends the law relating to the disposition of dead bodies by, among other things, making available for distribution to medical schools for dissection purposes, by the Board of Anatomy, the bodies of Confederate soldiers and of soldiers, sailors and marines of the World War and their wives. Such bodies were not available under the prior law.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

State Medical Meeting—The fifty-second annual meeting of the Arizona State Medical Association will be held at the Pioneer Hotel, Tucson, April 30 May 1 under the presidency of Dr. E. Payne Palmer, Phoenix. The preliminary program includes the following speakers:

- Dr. Clarence E. Rees, San Diego, Calif.: A New Method of Tendon Suture.
- Dr. Charles S. Kubler, Tucson: Demonstration of Heart Disease.
- Dr. Adrian E. Clark, Globe: A Case of Brunt's Disease with Apparent Recovery.
- Dr. E. Henry Running, Phoenix: Vomiting During the First Few Days of Life.
- Dr. Melvin I. Kent, Mesa: Intractable Clostridia—Report of a Case.
- Dr. James M. Owens, Phoenix: Herniated Intervertebral Disk: Diagnosis and Treatment.
- Dr. Archie P. Kimball, Yuma: An Outline of the Medical and Surgical Aspects of Commonly Used Sulfonamides.
- Dr. James Lytton Smith, Phoenix: Common Errors of Orthopedic Surgery.
- Dr. Howard C. James, Tucson: Maternal Deaths.
- Dr. Alexander N. Shoun, Benson: Rheumatic Heart Disease in Arizona.
- Dr. Paul Henry Case, Phoenix: Recent Advances in Ophthalmology of Interest to the General Practitioner.
- Dr. Charles A. Thomas, Tucson: Collapse Therapy for the Treatment of Tuberculosis in Patients of Advanced Years.
- Dr. Archie E. Cruthirds, Phoenix: A Brief Summary of the Present Treatment of Chronic Sinusitis.
- Dr. Philip H. Loveless, Morenci: A Case of Abdominal Pregnancy.
- Dr. Earle W. Phillips, Phoenix: Relief of Allergic Premenstrual Headache.
- Dr. Victor S. Randolph, Phoenix: Results of Thoracoplasty—A Five and Ten Year Study.

CALIFORNIA

Court Nullifies Revocation of License—A writ of mandate, issued by the San Francisco Superior Court, nullifying the revocation of the license of Dr. George C. H. McPheters, Fresno, by the state board of medical examiners has been entered in the medical register in the Fresno County clerk's office, newspapers reported February 6. Dr. McPheters' license to practice was revoked by the state board Oct. 21, 1942 following a hearing in Sacramento in which he was said to have been found guilty of offering to procure an abortion.

Increase in Infant Mortality—With 21 infant deaths reported for the week ended March 13, the San Francisco Department of Public Health announces a new high in infant mortality. This group brings the total for the first ten weeks of the year to 120 infant deaths under 1 year. 50 for January, 38 for February and 32 for the first two weeks of March. The department points out that of the 120 deaths, 27 were among nonresidents of the city and county of San Francisco. Fifteen of the group of infants died from enteritis (under 2 years) and 10 of congenital heart disease. Thirty-four deaths were attributed to prematurity.

FLORIDA

Personal—Dr. Henry C. Palmer, Tallahassee, was guest of honor at a dinner recently in recognition of his completion of fifty years in the practice of medicine—Dr. Elmer Thomas Sellers, Jacksonville, was recently guest of honor at a gathering given to celebrate his fifty-sixth birthday. Dr. Robert B. Melfer, Jacksonville, was host to the one hundred and seventy-five physicians who attended—Dr. Noble A. Upchurch, who has been health officer of Jacksonville since 1925, resigned January 1 on account of ill health. He has been succeeded by Dr. Wieland W. Rogers, who has been connected with the department for about fourteen years—Dr. P. J. McClellan was recently appointed health officer of Vero Beach.

Resolution on Temporary Licenses—The Lake County Medical Society on March 4 expressed its opposition to the licensing of or granting temporary permits to physicians who have not provided themselves with licenses through the regular channels provided by the state laws, except in counties in which there is an actual shortage of physicians. The society recommended that the county medical society in that county in which "emergency exists" shall request that a temporary permit be granted to physicians who have not provided themselves for licenses through the regular state channels. The resolution adopted by the society urged that such temporary

permits be terminated at the end of the present emergency. The society expressed its agreement with the state board of medical examiners in its effort to protect the interests of Florida licensed physicians both at home and in the armed forces.

NEVADA

New Secretary of State Association—Dr. Moreton J. Thorpe, Reno, has been appointed secretary of the Nevada State Medical Association to succeed Dr. Roland W. Stahl, Reno, who has been called to active military duty. Dr. Thorpe graduated at the University of California Medical School, San Francisco, in 1932.

NEW HAMPSHIRE

Personal—Dr. Gene B. Haber, formerly of Philadelphia U. S. Public Health Service, was recently assigned as health officer of the Eastern District of the New Hampshire State Board of Health with headquarters at Exeter. He succeeds Dr. Edward W. Colby, who is now in charge of the division of epidemiology of the state board of health at Concord.

Name of Department of Health Changed—Under the terms of a recently enacted law which becomes effective on July 1 the state board of health is for administrative purposes to be officially known as the "State Department of Health of New Hampshire." The title of the executive officer will be state health officer instead of secretary as in the past. The act also prescribes that the latter who also serves as secretary to the board, shall be a physician and a person with knowledge of and experience in public health work and sanitary science and shall be the registrar of vital statistics of the state. As in the past the board is composed of the governor and the attorney general as ex officio members and with five others of whom three are physicians, one a civil engineer and one who is neither a physician nor a civil engineer (the latter at the present time a pharmacist). According to *New Hampshire Health News* a new division of diagnostic laboratories is now located at the state hospital, Concord.

NEW JERSEY

Dr. John Baker Lectures for Cereal Chemists—John C. Baker, Ph.D., chief chemist of Wallace & Tiernan Company, Inc., Newark, was chosen by the American Association of Cereal Chemists to lecture throughout the country on "Gluten and Its Relation to Flour Constituents in Bread Making." Dr. Baker spoke in Columbus, Ohio, March 27; Fort Worth, Texas, March 31; Manhattan, Kan., April 3; Winnipeg, Canada, April 5; Minneapolis, April 7; and Chicago, April 9. This is the second year that the American Association of Cereal Chemists has chosen one of its members to lecture to its sections throughout the country on special research work.

NEW YORK

County Society Votes to Bar Alien Physicians—The Erie County Medical Society recently unanimously voted to bar from its membership "physicians who are not United States citizens." The action was taken "to protect the postwar interests of the physicians called to war," it was reported.

Amebic Dysentery at State Hospital—An investigation is under way at Creedmoor State Hospital, Queens Village, to determine the cause of an outbreak of amebic dysentery. Since last June 97 cases have occurred. Of this number 16 patients and 6 employees had been "clinically sick," with 11 employees and 26 patients mildly affected, newspapers reported. In addition 38 "carriers" of the organism were found. On March 18 only 1 person at the hospital was actually ill with the disease, although 35 to 40 patients and employees were still isolated.

New York City

Personal—Dr. Howard Fox has been appointed consultant in tropical medicine to the Secretary of War—Dr. Thomas A. Gonzales, chief medical examiner of the City of New York, has been made an honorary member of the Asocacion Medica Argentina.

Physicians' Orchestra Suspends Activities—The Doctors Musical Society of Brooklyn has been compelled to suspend activities for the duration because of the loss of many of its members to the armed services.

Missing in Action—Capt. A. Leonard Hymes, M. C., Army of the United States, Brooklyn, while on active duty with the air corps somewhere in the South Pacific has been reported missing in the service of his country. Captain Hymes graduated at the New York University College of Medicine in 1939.

The First Bela Schick Lecture—Dr William E Ladd, professor of child surgery, Harvard Medical School Boston, will deliver the first Bela Schick Lecture at Mount Sinai Hospital, April 13. His subject will be 'Time and Choice of Operation in Early Life'. The lecture is one of a series planned in honor of Dr Bela Schick now consultant and formerly pediatrician in chief at the Mount Sinai Hospital and is made possible by a fund contributed in 1942 by friends and associates of Dr Schick.

OHIO

Missing in Action—Lieut Aaron S Michelson Cincinnati, medical officer of the destroyer U S S *Laffey* has been officially reported missing. The *Laffey* was one of seven U S destroyers lost in an engagement at Guadalcanal. Press reports indicate that Lieutenant Michelson was trapped below deck while helping remove wounded sailors from the doomed vessel. Before entering the Navy in May 1942, he had been chief resident at the Jewish Hospital, Cincinnati and assistant clinician in general medicine at the Cincinnati General Hospital.

Personal—William S Keller senior surgeon, U S Public Health Service Reserve regional medical officer, Fifth Civilian Defense Region, Cleveland recently bestowed a citation on Dr Clyde M Fitch chief of emergency medical service in Portsmouth and Dr Orville J Walker, chief of emergency service in Youngstown for "outstanding accomplishments and efficiency in organizing the civilian defense setup"—Dr Irvin Abell, Louisville, Ky, was presented with an honorary degree of doctor of laws during the recent annual commencement of the University of Cincinnati College of Medicine.

Institute of Medical Research Dedicated—The Institute of Medical Research at the Toledo Hospital, Toledo was dedicated on March 27. The institute is housed in a new two story building made possible by an endowment from the late Frank Collins of the National Supply Company, Toledo. The staff includes a biochemist, nutritionist, bacteriologist, pathologist and biophotographer under the direction of Dr Bernhard Steinberg, Toledo. The staff will be augmented by a physiologist, biophysicist and pharmacologist. Provision has been made to accept fellows in medical and dental research. The institute will not be devoted to the study of a single disease but will maintain interest in diseases in general, depending on the availability of the personnel. Dr Cyrus C Sturgis professor of internal medicine and director of the Thomas Henry Simpson Memorial Institute for Medical Research University of Michigan Medical School, Ann Arbor, gave the dedicatory address on "The Future of Medical Research". Other speakers included Frank Adams, chairman of the research board, Reverend Russell J Humbert, pastor of the Epworth Methodist Church, and the Honorable Lloyd Roulet, mayor of Toledo.

PENNSYLVANIA

Society News—Dr Benjamin H Shuster, Philadelphia discussed vertigo before the Reading Eye, Ear Nose and Throat Society recently. At a meeting of the Fayette County Medical Society in Uniontown, April 1, Dr Joseph V Marnell spoke on diagnosis and management of deep neck infections.

Philadelphia

Committee on Physicians' Health—The Commission of Physicians' Health of the Philadelphia County Medical Society has been temporarily disbanded because of the number of physicians in the vicinity who are in the armed forces and the death of the chairman of the commission Dr James Alexander Clarke Jr. One of the commission's principal objectives was to carry out periodic health examinations of members of the society.

Annual Postgraduate Institute—The Philadelphia County Medical Society will hold its eighth annual postgraduate institute at the Benjamin Franklin Hotel, May 11-14. About seventy speakers will participate, their presentations covering a wide range of medical subjects. On Monday evening May 10 a joint meeting of the Philadelphia Health Association and the section on medicine of the Philadelphia College of Physicians will be addressed among others by Dr Clarence E de La Chapelle New York, on the 'Treatment of Coronary Thrombosis'.

Herbert Fox Memorial Fellowship—David L Coffin, DVM, instructor in veterinary pathology at the University of Pennsylvania, has been appointed to the Herbert Fox Memorial Fellowship in comparative pathology at the Zoological Society of Philadelphia. Dr Coffin who is the first incumbent of the fellowship, will serve as assistant to Herbert L Ratcliffe ScD, recently appointed director of the Penrose Research Laboratory of the Zoological Society and assistant

professor of comparative pathology at the University of Pennsylvania. The fellowship was established in 1942 by the Zoological Society in memory of Dr Herbert Fox, pathologist and director of the Penrose Laboratory from 1907 to 1942 and professor of comparative pathology at the university from 1927 to 1942. It provides for half time work at the Zoological Garden by faculty members of the School of Veterinary Medicine of the university who are interested in the diseases of wild animals.

Pittsburgh

Hospital News—A new addition to St Joseph's Hospital and Dispensary costing \$500,000 was opened on March 19. The new unit offers advanced facilities for the treatment of pediatric, gynecologic and maternity patients as well as for general and special x-ray diagnosis and therapy. The hospital, with the new addition now has a capacity of 250 beds.

Society News—The Pittsburgh Surgical Society was addressed March 25 by Drs Theodore S Swan on 'Surgical Aspects of Diverticulitis'. William S McElroy dean of the University of Pittsburgh School of Medicine. Effect of the Army and Navy Collegiate Program on Medical Education and Herbert Frankenstein, 'Acute Inflammation of the Appendices Epiploicae'.

VERMONT

New Blood Bank at Medical School—A blood plasma bank was formally opened on March 19 in space provided by the University of Vermont College of Medicine Burlington. The bank is a cooperative one in which the state contributed \$3000 of the \$30000 which was collected in a statewide campaign. Dr Wendell E James, associate professor of bacteriology and clinical pathology at the school is director of the bank and processing laboratory. There are fourteen hospitals in the state that are cooperating and the bleeding is to be done at these hospitals, the donors registering with the local Red Cross agencies. The blood is to be shipped to the laboratory for processing and each hospital is allocated 1 unit for each bed until the total bank reaches 2000 units. Plasma will be available not only for civil defense but for civilian needs also and if, as is expected there is a surplus above this point it will be donated to the military service.

VIRGINIA

Stuart McGuire Lectures—Dr Philip D Wilson, clinical professor of orthopedic surgery, Columbia University College of Physicians and Surgeons, New York gave the fourteenth annual Stuart McGuire Lectures at the Medical College of Virginia, Richmond February 25-26, on 'The Treatment of War Injuries, Especially Compound Fractures' and 'Amputations in Wartime'. The lectures were given in conjunction with the spring postgraduate clinic, consisting this year of a symposium on low back pain. Speakers in the symposium included Dr Emil J C Hildenbrand associate professor of clinical surgery Georgetown University School of Medicine Washington D C from the point of view of the physical therapist and the following physicians from the staff of the medical school: Drs Henry Page Mauck professor of clinical orthopedic surgery, Claude C Coleman professor of neurologic surgery, James Asa Shield assistant professor of neuropsychiatry, and Randolph H Hoge, assistant professor of gynecology.

WEST VIRGINIA

Medical Consultant for Bureau of Hygiene—Dr Henry M Brown, industrial physician at the du Pont plant at Belle, has been appointed medical consultant for the bureau of industrial hygiene of the West Virginia State Department of Health. While he has been appointed to succeed Dr John W Crosson, who was director of the bureau until his resignation to become industrial consultant for Sharp & Dohme, Philadelphia, Dr Brown will serve in a consulting capacity only.

Personal—Norman H Baker DDS Charleston has been reappointed as the dental member of the Public Health Council of West Virginia for the term ending June 30 1945.—Dr Benjamin E Hodge, Clarksburg representing the West Virginia State Medical Association has been appointed a member of the West Virginia State Nutrition Committee succeeding Dr James Lewis Blanton Fairmont who has entered the U S Army Medical Corps.—Dr Erlond H Hedrick has been appointed medical superintendent of Pincrest Sanitarium Beckley succeeding Dr Kyle M Jarrell, who had held the position since 1933.

Committee to Study Medical Care and Hospital Service—A fact finding and planning committee has been appointed by Dr Robert J Wilkinson Huntington president of the state medical association, to study prepayment plans

providing medical care and hospital service. The appointment of the committee followed the recent passage of a bill providing for the operation of hospital service plans in West Virginia. The bill is effective only until Feb 28 1945 and the new committee will endeavor to draft a bill for introduction to the next session of the legislature that meets with the approval of the medical profession and hospitals in West Virginia. The committee will also study the possibility of establishing a full time trained health personnel for every county or group of counties in the state, the treatment and control of tuberculosis together with the problem of handling tuberculous patients and the management of state tuberculosis sanatoriums and hospitals for the treatment of mental diseases. Members of the new committee are Drs Ray M Bobbitt Huntington chairman Delvan A MacGregor Wheeling Thomas L Harris Parkersburg John P Helmick Fairmont Frank A Langfitt Clarksburg Carl E Johnson Morgantown Frank J Holmroed Princeton Benjamin H Swint Charleston and Hu C Myers Philippi.

GENERAL

Meetings Canceled—The American Society for Clinical Investigation has canceled its thirty-fifth annual meeting which was scheduled for Atlantic City May 3.—The Association of American Physicians has canceled its annual meeting scheduled for Atlantic City N. J., May 4-5.

Seek Apprehension of Male Nurse—Robert Edward White nurse and ex convict is wanted by the San Francisco Police Department because of an alleged theft of \$1400 from

Robert Edward White

a patient. White disappeared and according to Charles W Dullea chief of police of San Francisco, is expected to seek employment in a hospital as soon as the money is gone. His social security number is 526 22-9810. He is 42 years old, 5 feet 5½ inches tall weighing 150 pounds and has blue eyes and brown bushy hair. A peculiarity is that his eyebrows run across his nose. He is a native of Missouri. Any one recognizing this man is urged to communicate with the local police department immediately.

Lilly Prize Awarded to Dr Carter—Herbert E Carter Ph.D., assistant professor of chemistry, University of Illinois Urbana will be presented with the \$1000 Eli Lilly & Co Prize in biological chemistry for 1943 at the annual meeting of the American Chemical Society, Detroit April 14. Dr Carter who is 32 years of age was awarded the prize in recognition of his studies on amino acids, the building blocks of proteins and of fatty acids.

The Interne Continues Publication—The Association of Internes and Medical Students announces that despite a rapidly changing staff the *Interne*, the official journal of the association will continue publication, featuring articles on the armed services and other aspects of the war effort which are of particular interest to medical students and physicians. The present staff includes Dr Jerome M Schneek and Nathaniel Gottesman editors, Dr Kenneth L Zierler Baltimore features, Dr John L Simon Brooklyn books, Dr Leon N Greene New York humor, and Mr Julian Farren managing editor. Communications should be addressed to Dr Schneek, 40 East Tenth Street New York.

CANADA

Woman Graduate Honored—Dr Augusta Stowe Gillen, Toronto, Ont., reported in the *Canadian Medical Association Journal* as the first woman to obtain her medical degree from a Canadian university was recently paid special tribute in recognition of her sixtieth anniversary of graduation from medical school. Dr Gillen's mother, Dr Emily Howard Jennings Stowe was the first woman to practice medicine in Canada but she obtained her degree in New York according to the Canadian journal. At the opening of the Ontario Medical College for Women Toronto Dr Gillen was appointed demonstrator of anatomy, later lecturer on children's diseases and subsequently professor of pediatrics a position she held until the women's medical college was amalgamated with the University of Toronto. She served in the senate of the University of Toronto from 1910 to 1922.

Canadian Association Holds Special Meeting of Council—For the first time the council of the Canadian Medical Association called a special meeting, January 18-19 to discuss health insurance and other urgent matters under consideration by the executive committee. Unanimous approval was given to a resolution that the association adopt the principle of health insurance favoring a plan 'which will secure the development and provision of the highest standard of health services, preventive and curative in such plan be fair both to the insured and to all those rendering the services.' At this meeting a report of the department of cancer control was submitted which urged that cancer be made a reportable disease in the Dominion and the appointment of a commission whose responsibilities would be to correlate all data incident to cancer for educational and statistical purpose, to establish cancer treatment centers to administer all grants and requests for cancer work to concern itself with the problem of the transportation of patients who live at a distance from a treatment center and to foster research in cancer. The association decided to let its annual meeting in Montreal take the form of a business meeting, the executive committee will meet June 12-13 and the general council June 14-15.

Deaths in Other Countries

Major General Amin Fahd Maluf Pasha M.D. formerly principal medical officer of the Iraq army, died at his home in Helopolis Egypt on January 21 in his seventy-first year. He began his career in military medicine as an officer in the Egyptian army and served a few years in the Sudan. On the Arabian revolt in the last war he resigned his position in the Egyptian army and joined King Faisal's troops as a surgeon. He was decorated ten times. A graduate of the American University Beirut Major General Maluf was elevated from a colonelcy and created a pasha on his retirement about fifteen years ago. His latest works are 'An Arabic Zoological Dictionary' and 'An Astronomical Glossary.'

Government Services

Dr Sherman Heads Bureau of Human Nutrition

Henry C Sherman Sc.D. Mitchell professor of chemistry, Columbia University, New York, has been appointed head of the newly established bureau of human nutrition and home economics of the United States Department of Agriculture, Washington, D.C. Dr Sherman has been at Columbia University since 1897.

Dr DeLien Named Assistant in Office of Indian Affairs

Dr Horace DeLien, special expert in tuberculosis in the Office of Indian Affairs has been appointed assistant to the director of health, Dr John R. McGibony, Chicago, succeeding Dr Lawrence W White, Chicago. Dr DeLien graduated at the University of Minnesota Medical School, Minneapolis in 1933 and engaged in private practice in Mohridge, S.D. for several years. Prior to entering the Indian Service in 1938 he was director of the Pennington County Health Unit in South Dakota, with headquarters in Rapid City. In 1941 he was transferred from his work as special physician in tuberculosis control of the Indian Service for California, Nevada and Utah to additional responsibilities as special expert in tuberculosis.

Nutrition of Infants and Children in Wartime

The nutrition of infants and children in wartime was discussed at the latest meeting of the Swiss Society of Pediatrics. On the basis of the papers read the resolutions stressed the importance of breast milk for nurslings. Adults can live without milk, children cannot. All milk products are to be reserved for infants and patients, and their sale to other persons is to be prohibited. A ration card for infants and a similar one for children to the end of the fifth year of life were proposed. They provide the following:

(a) A rationing card for infants which is to be used to the end of the first year of life

	Per Day	Per Month
Milk	660 Gm	20 liters
Sugar	40 Gm	1 200 Gm
Rice	20 Gm	600 Gm
Grits	20 Gm	600 Gm
Flour	20 Gm	600 Gm
Butter	10 Gm	300 Gm
Cheese	5 Gm	150 Gm
Cocoa or tea		100 points
Eggs		2

(b) A ration card for children, which is to be used to the end of the calendar year in which the child completes its fifth year

	Per Month
Cereaceous foods	
Rice, oats or barley	750 Gm
Flour, grits, maize	750 Gm
Baked foods	250 Gm
Bread	4 500 to 6 000 Gm
Sugar	1 000 Gm
Milk	20 liters
Oil or fat	100 Gm
Butter	400 Gm
Potatoes	4 500 Gm
Cheese	150 Gm
Meat	500 Gm
Legumes	100 Gm
Eggs	4
Cocoa or chocolate	200 points

Lactic acid is to be reserved for the preparation of lactic acid milk for nurslings and for the preparation of lactic acid powdered milk.

Pediatricians have lodged a complaint regarding the advertising methods of manufacturers of special food preparations for children. The pediatric society passed a resolution which objected to the practice of certain producers of special nutrient substances for children. The resolution points out that their propaganda methods are no longer compatible with the welfare of the population in general. It is intolerable that representatives of these manufacturers or children's nurses who have been hired for the purpose, urge mothers to depart from the food formulas prescribed by physicians and use their canned products instead.

Swiss pediatricians emphatically object that physicians or the editors of periodicals who point out that the healthy child does not need special nutritional preparations and that they represent an unnecessary increase in food costs are called to account by these manufacturers of special nutrient substances and are threatened with legal and economic reprisals.

Swiss pediatricians are of the opinion that manufacturers of nutrient substances are not dependent on such methods of advertising and therefore urge these firms to refrain from this practice.

Feeding of Patients Under Swiss Food Rationing

A committee for war nutrition has existed in Switzerland since the beginning of the war. Prof. Dr. Alfred Fleisch, physiologist of the University of Lausanne is its president. This committee has formulated guiding principles for physicians on the feeding of patients under food rationing. In October 1942 new regulations became necessary because the food supply of the country had taken an unfavorable turn and a number of new measures became necessary, for instance bread and milk had to be included in the rationing. Whereas formerly 3 000 calories was regarded as a basis for the daily requirements, it became necessary to reduce it to 2 400 calories (protein 80 Gm, fat 55 Gm and carbohydrates 400 Gm). Additions can be granted only if the health of a person makes this absolutely essential. Excessive special grants may jeopardize the entire food balance of the country. Instead of computing optimum figures the physician must now consider minimum figures.

Exact regulations have been formulated with regard to permits for additional rations by physicians. These are based as far as possible on the principle of compensation, that is one food is exchanged against another one that is more suitable in the particular disorder. The measures to effect savings go so far that for bedridden patients from 1 800 to 2 000 calories is estimated as adequate. Only patients with prolonged disorders are entitled to special rations. For short illnesses rations are not usually granted. Convalescents likewise are not entitled to special rations. Only five groups of patients are to receive special rations: those with gastrointestinal disorders, diabetes, hepaticobiliary disorders, renal diseases and tuberculosis. In other types of disorders special rations are to be granted only in exceptional cases. Officially approved physicians are to make the decisions regarding requests for special rations. A detailed table has been made up to estimate rations for patients and this table has been further amplified by special regulations. These amplifications are concerned with the granting of eggs instead of meat, with nutritive preparations, children's foods, coffee, tea, cocoa, honey and oils and fats for medical purposes. Other regulations are concerned with the consumption of meat on meatless days, special rations for blood donors, white bread for persons with gastrointestinal disorders, children's rations, sweetening substances for diabetic patients and so on. All this indicates that in Switzerland it has become necessary to introduce extreme restrictions even as regards patients.

Porphyrins in the Healing of Wounds

Prof. Dr. Emil Buerger of Bern discussed the use of porphyrins in the healing of wounds in the Medical Society of Bern on the basis of observations made in the Pharmacologic Institute of which he is the head. The porphyrin ring develops when four pyroles are linked together by CH groups. Depending on whether the free valences of the N atoms in the ring are replaced by iron or magnesium there develops blood pigment, chlorhemum or chlorophyll.

The tonizing and wound healing action of the porphyrins was studied in 300 rabbits in which two pieces of skin were cut out on symmetrical sites of the back. The defects were subjected to comparative treatment by porphyrin ointments, pure ointment bases and other ointments. The efficacy of the examined substances could be estimated only on the basis of rapidity and perfection of the resulting regeneration because every wound left to itself heals automatically. Furthermore, individual differences in the reaction capacity of the individual animals had to be considered.

Studies were made on chlorophyll, blood pigments and muscle porphyrins. The raw chlorophylls, the pure extracts as well as the water soluble chlorophyll sodium which contain magnesium in the porphyrin ring, have an excellent curative effect on

wounds. Other plant pigments such as carotene and vitamin A have only a slight effect, and riboflavin and vitamin C have no influence at all.

The blood pigments exert the same effect on wounds as does chlorophyll. However, it is peculiar and unexplainable that the nonferric derivatives of hemoglobin, hematoporphyrin and even bilirubin have a noticeable healing effect on wounds, whereas phenophytin, which is free of magnesium, has no effect whatever. The muscular porphyrins and muscular pulp were found extremely effective. The porphyrins greatly stimulate the formation of granulations, but they influence epithelialization only slightly. Their toxicity is negligible. A disinfecting action of the porphyrins could not be ascertained, in contradistinction to the observation of the American Gruskin.

BRAZIL

(From Our Regular Correspondent)

March 17, 1943

Vital Statistics of Rio de Janeiro

Provisional vital statistics for the city of Rio de Janeiro for the year 1942 are now available. The figures may be compared to those for 1941 (*THE JOURNAL*, May 2, 1942, p. 96). The population of the city as of July 1, 1942 was 1,853,264. The number of deaths from all causes was 32,502, giving an annual crude death rate of 17.54 per thousand of population, which is slightly lower than that of the previous year (17.89) and that of the average for the five year period 1937-1941 (17.60). The number of live births registered was 39,211, giving a birth rate of 21.15, which is a much better figure than that of the previous year (19.28). The vital index was 121, an improvement over the 1941 figure (108). The number of deaths in the age group 0-1 year was 6,015, which corresponds to the high rate of 153 infant deaths per thousand live births, nevertheless a little better than the rate for the previous year (180). The fetal mortality was 77.73 per thousand total births, as 3,304 stillbirths have been registered. The number of deaths from causes related to pregnancy, childbirth and the puerperium was 304 corresponding to a maternal mortality rate of 7.75 deaths per thousand live births, or 1 maternal death in 129 live births.

First as a cause of death are "all forms of tuberculosis," with a total of 5,773 deaths (5,606 from tuberculosis of the respiratory apparatus), or 17.76 per cent of the total of deaths from all causes—a crude specific death rate of 312 per hundred thousand of population as against 316 in the previous year. Tuberculosis is still a very important problem of the city in spite of the efforts made by the health department in the past years. The rest of the "infectious and parasitic diseases" caused 4,571 deaths, which, with the deaths from tuberculosis, gives a total of 10,344 deaths from infectious and parasitic diseases (31.83 per cent of the deaths from all causes). Of this total 116 were from typhoid, which corresponds to an annual death rate of 6.26 per hundred thousand, against 7.17 in 1941 and 7.10 in the five year period 1937-1941. The other principal infections were dysentery, mainly bacillary, with 334 deaths (18.02 per hundred thousand), measles with 322 deaths (17.37 per hundred thousand), whooping cough with 277 deaths (14.95 per hundred thousand), diphtheria with 143 deaths (7.72 per hundred thousand), malaria with 195 deaths (10.52 per hundred thousand), influenza with 1,222 deaths (65.94 per hundred thousand), leprosy with 52 deaths (2.81 per hundred thousand) and poliomyelitis with 3 deaths (0.16 per hundred thousand). Tetanus (about 50 per cent umbilical) caused 210 deaths (11.33 per hundred thousand). The annual death rates from these infections for 1941 and for the five year period 1937-1941 were respectively,

dysentery 14.06 and 14.40 per hundred thousand, measles 12.02 and 14.61, whooping cough 15.60 and 15.42, diphtheria 10.59 and 8.41, malaria 12.07 and 12.50, influenza 60.65 and 55.30, leprosy 3.14 and 3.62, poliomyelitis 0.05 and 0.41 and tetanus 11.69 and 10.11. In 1942 cancer caused 1,248 deaths, or 67.34 per hundred thousand (66.44 in 1941), thus being on a continuous increase since 1903-1907, when the mean annual crude death rate was 34.75.

The second most important single group of causes of death is that of the diseases of the circulatory system, represented by a total of 5,717 deaths, or 17.59 per cent of the deaths from all causes, which corresponds to the rate of 308 per hundred thousand (308 in 1941). Out of this total 4,533 deaths have been reported as due to diseases of the heart which corresponds to the rate of 245 per hundred thousand (217 per hundred thousand in 1941). This represents a new increase in the number of deaths from diseases of the heart. The crude annual specific death rate from diseases of the cardiovascular system is on a rapid increase in Rio de Janeiro as clearly shown by these figures: 178 in 1932-1936, 235 in 1937-1941 and 308 in 1942.

The third leading group of causes of death is that of the diseases of the digestive apparatus represented by 5,139 deaths, or 15.81 per cent of the deaths from all causes which corresponds to the rate of 277 deaths per hundred thousand of population (275 in 1941). The bulk of these deaths is reported under the title of "diarrhea and enteritis under 2 years" (3,573 deaths), which is the largest contribution to the infant mortality—an average of 39 per cent of the infant deaths in Rio de Janeiro are classified as due to diarrheal diseases. The number of deaths registered as caused by appendicitis was 99 (102 in 1941), and that caused by diseases of the liver and the biliary ducts was 409 (418 in 1941), which correspond respectively to 5.34 and 23.63 per hundred thousand of population. The diseases of the nervous system have caused 1,222 deaths, or 65.94 per hundred thousand (71.17 in 1941), the largest contribution being from "intracranial lesions of vascular origin" (876 deaths, or 47.27 per hundred thousand). The total number of deaths registered as caused by diseases of the respiratory apparatus was 3,724 or 11.45 per cent of the total from all causes, and a death rate of 201 per hundred thousand (215 in 1941). The diseases of the genitourinary system have caused 1,431 deaths, or 4.40 per cent of the total from all causes which corresponds to 77.21 per hundred thousand (74.93 in 1941).

Puerperal septicemia and infection were the cause of 126 deaths, or 41.45 per cent of the maternal deaths (one death in 321 live births as against one in 282 in 1941). Violent deaths were 1,214, or 3.73 per cent of the total of deaths from all causes, which corresponds to the rate of 65.51 per hundred thousand (66.44 in 1941). Out of this total, 198 deaths have been caused by motor vehicle accidents, or 10.68 per hundred thousand, as against 17.92 in 1941, the decrease corresponding to the sharp reduction in automobile traffic due to gas rationing.

Marriages

JOSEPH A. FIORITO, New Haven, Conn., to Miss Edith Patricia Hawley of Montreal, Que., Canada, March 18.

EDWARD GORDON BILL, Jr., Bronxville, N. Y., to Miss Rose Elizabeth Hynes of New York, March 23.

OSCAR GARFELD to Mrs. Martha Carr Moon, both of Chicago, in Carson City, Nev., recently.

REUBEN LEASS, Frammingham, Mass., to Miss Mae Kripke of Boston, March 21.

HARRY E. GRANT, Easton, Ill., to Miss Marietta Crosthwait of Chicago in March.

Deaths

Grant Charles Madill © Ogdensburg, N Y, long a member of the House of Delegates of the American Medical Association, died, March 26 of myocarditis and cerebral hemorrhage aged 78. Dr Madill was born in Stockton, Calif, July 6 1864. His early education was received at the Ogdensburg Free Academy, Potsdam, N Y, and the state normal school. In 1886 he graduated at the Bellevue Hospital Medical College, New York. Following his internship at the Presbyterian Hospital and Sloane Hospital for Women, New York. Dr Madill joined the staff of the A Barton Hepburn Hospital, Ogdensburg, serving there as chief surgeon since 1888.

Dr Madill was a regent of the University of the State of New York, a fellow of the American College of Surgeons a member of the New York Academy of Medicine American Association for the Advancement of Science and the Alumni Association of New York University. In 1908 he received a doctor of laws degree from the St. Lawrence University, Canton N Y, and in 1932 one from New York University. He was president of the Medical Society of the State of New York in 1919, serving as trustee from 1926-1935. In 1925 he was president of the St. Lawrence County Medical Society. Dr Madill had been first vice president of the St. Lawrence County Savings Bank and director of the Ogdensburg Trust Company. He was a member of the House of Delegates of the American Medical Association from 1912 to 1913, from 1922 to 1935 and from 1937 to 1940. He served as captain in the medical reserve corps of the U S Army, 1917-1918.

Clifton Meredith Miller © Richmond, Va, Medical College of Virginia Richmond, 1892, associate professor of otolaryngology at his alma mater specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology, member of the House of Delegates of the American Medical Association in 1912 member of the American Laryngological Rhinological and Otolological Society and the American Otolological Society. In fellow of the American College of Surgeons past president of the Richmond Eye Ear Nose and Throat Society, Virginia Ophthalmological and Otolaryngological Society and the Richmond Academy of Medicine, served as a member and vice chairman of the city school board of Richmond local ophthalmologist, Seaboard Air Line Railway member of the board of directors, ophthalmologist and otolaryngologist on the staff of the Stuart Circle Hospital visiting surgeon, department of otolaryngology, Memorial Hospital, aged 69, died, February 26, of carcinoma of the prostate.

Thomas Joseph O'Leary © Superior, Wis, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906 past president of the State Medical Society of Wisconsin, the Douglas County Medical Society and the Interurban Academy of Medicine, councilor and past president of the Eleventh District of the State Medical Society, surgeon for the Great Northern and Soo Line railroads for many years, fellow of the American College of Surgeons, president of the Wisconsin State Bank and the Selective Service advisory board chief of staff of St. Joseph's Hospital on the staffs of St. Francis Hospital and St. Mary's Hospital where he died February 26, of coronary thrombosis, aged 61.

Ralph Rust Wilson © Kansas City, Mo Harvard Medical School, Boston 1921, specialist certified by the American Board of Obstetrics and Gynecology Inc, member of the Central Association of Obstetricians and Gynecologists, past president of the Kansas City Academy of Medicine and the Kansas City Obstetric and Gynecological Society for many years chairman of the committee on maternal welfare of the Missouri State Medical Association chief of the obstetric and gynecologic service at the Kansas City General Hospital, served on the staffs of the Menorah Hospital, Trinity Lutheran Hospital and St. Luke's Hospital, where he died, February 6 of coronary thrombosis, aged 46.

Clarke Sullivan, Dayton Ohio, Chicago Homeopathic Medical College 1904 member of the Ohio State Medical

Association, first chairman and first president of the Dayton Obstetrical Society, during World War I served as a captain in the medical corps of the U S Army and as assistant chief of staff at Base Hospital, Camp Sherman Chillicothe served on the courtesy staff of St. Elizabeth and Good Samaritan hospitals, member of the board of trustees, member of the consulting staff and for many years chief of the obstetrical staff of the Miami Valley Hospital, where he died suddenly, February 13, of acute dilatation of the heart, aged 65.

Charles Walter Waddell © Fairmont, W Va Harvard Medical School, Boston, 1907 specialist certified by the American Board of Internal Medicine, in 1938 president of the West Virginia State Medical Association, member of the State Advisory Board Department of Public Assistance and examiner for the State Compensation Commission member of the medical advisory board number 3, West Virginia Selective Service, fellow of the American College of Physicians director of the chemical laboratory and member of the staff of the Fairmont General Hospital, aged 65 died March 29.

Elizabeth M Baer, Roselle Park, N J, Hahnemann Medical College and Hospital Chicago, 1898, aged 81 died, January 25, in the Belle Mead Sanatorium and Farm Bellemead of coronary sclerosis.

George Le Roy Brown, Chicago, Chicago Homeopathic Medical College 1899 veteran of the Spanish-American War, aged 66, died February 28, in the Passavant Memorial Hospital of cardiac failure and hypertension.

Julius J Buel, Lakewood, Ohio, Universität Bern Medizinische Fakultät Switzerland 1885, a charter member of the staff of Lutheran Hospital, Cleveland and for many years on the staff of St. John's Hospital, Cleveland, aged 82 died January 18 of cerebral hemorrhage.

George Fletcher Bullard © Elizabethtown N C, North Carolina Medical College, Charlotte, 1915 aged 55 died, January 17 in the Veterans Administration Facility Fayetteville, of carcinoma.

Herbert G Cabbell, Lawrence, Kan Jenner Medical College, Chicago, 1912 member of the Kansas Medical Society, aged 55 died, January 13, of valvular heart disease.

Erasmus Taylor Camp, Gadsden, Ala Medical College of Alabama, Mobile 1885 member of the Medical Association of the State of Alabama past president of the Etowah County Medical Society at one time county health officer formerly a physician in charge of the Camp and Ralls' Hospital aged 93 died February 9, of prostatic obstruction and uremia.

Lawrence Cauffman, Masonville, N J, Medico Chirurgical College of Philadelphia 1890, aged 73 died January 25 of cardiovascular renal disease.

Guy Chappell, Dawson, Ga, Atlanta Medical College, 1897 member of the Medical Association of Georgia chairman of the Selective Service Board and county physician past president of the Terrell County Medical Society, a captain in the medical corps of the U S Army during World War I, aged 67 died, January 15, of carcinoma of the prostate.

Morton Clofine © Philadelphia Long Island College of Medicine Brooklyn 1937 diplomate of the National Board of Medical Examiners member of the Philadelphia Obstetrics Society associate in gynecology at the University of Pennsylvania Graduate School of Medicine, on the staffs of the Mount Sinai St. Agnes and the Graduate Hospital of the University of Pennsylvania where he died February 18 of abdominal lymphosarcoma with metastases, aged 29.

Solomon David Deren © Syracuse, N Y University of St. Vladimir Faculty of Medicine, Kiev Russia, 1913 Syracuse University College of Medicine, 1924 served on the staff of the Syracuse State School, aged 61, died, January 5, of coronary occlusion arteriosclerosis and hypertension.

John Vardeman Dillman, Louisville, Ill, Missouri Medical College St. Louis, 1899 member of the Illinois State Medical Society, served during World War I in the medical corps of the U S Army for several years president of the Clay County State Bank of Louisville aged 73 died, February 11, of cardiorenal disease.

GRANT CHARLES MADILL, M D
1864-1943

John Otho Downey, New York, University of Pennsylvania Department of Medicine, Philadelphia, 1906 at one time a surgeon, lieutenant commander, U S Navy served during World War I, aged 59, died, February 2, in St Luke's Hospital of coronary thrombosis

Howard Paul Durbin ♂ Kirkwood, Mo St Louis University School of Medicine, 1927, aged 46, died January 17, of coronary occlusion

Thomas Burnham Enders ♂ Mystic, Conn, College of Physicians and Surgeons, New York, 1891, aged 77 died, January 25, in the Lawrence and Memorial Associated Hospitals, New London of chronic nephritis, arteriosclerosis and duodenal ulcer

Charles Schuyler Harper, Berryville, Ark, Barnes Medical College, St Louis 1909, also a pharmacist received the doctor of public health degree from Tulane University New Orleans in 1916, aged 64, died, February 16, of heart disease

Allen Fitch Higgins, Tampa, Fla, Northwestern University Medical School Chicago, 1902, physician of Hillsborough County for many years served in the medical corps of the U S Navy during World War I, aged 67, died February 3 in the Veterans Administration Facility, Bay Pines of cerebral hemorrhage and arteriosclerosis

Andrew Jackson Irwin, Sandersville Ga University of Georgia Medical Department, Augusta 1884, aged 80 died January 25, of heart disease

Homer Bates Jester ♂ Corsicana Texas College of Physicians and Surgeons Baltimore, 1901 president of the Navarro County Medical Society, past president of the Central Texas District Medical Society, served as a major in the medical corps of the U S Army during World War I for many years a member of the Navarro Clinic a member of the board of directors of the State National Bank aged 67 died January 26 of coronary occlusion

Rolfe Kingsley, New York Columbia University College of Physicians and Surgeons New York 1906 associate in urology at his alma mater from 1924 to 1926 served as a genitourinary surgeon on the staff of the Presbyterian Hospital aged 61 died February 4, of cerebral hemorrhage

John August Kussman, Piqua Ohio Medical College of Ohio, Cincinnati, 1889 aged 76, died January 16

Fannie Lanham, Chicago Chicago College of Medicine and Surgery 1913 a founder, a member of the board of trustees and for many years on the staff of the Women's and Children's Hospital aged 71 died January 27 at the home of her niece in Peoria Ill of carcinoma

Albert H Lanzer ♂ Cleveland Heights Ohio University of Wooster Medical Department, Cleveland 1905 aged 65 died January 16, of carcinoma

Charles Lester Large, Portland Ore College of Physicians and Surgeons, Keokuk, Iowa, 1880 aged 87 died January 15, of cerebral hemorrhage

Otto W Lewke, Chicago, Chicago Medical College, 1889 member of the Illinois State Medical Society chief physician to the coroner of Cook County from 1902 to 1909 member of the board of directors of the Chicago Public Library and vice president from 1897 to 1901 on the staff of the Northwestern American Hospital, aged 76, died, March 7, of coronary thrombosis

Washington E Linden, Cleveland Western Reserve University Medical Department, Cleveland, 1883 formerly member of the county board of health, aged 84 died, January 8 of lobar pneumonia

John Othello Logan ♂ New York, Columbia University College of Physicians and Surgeons New York, 1898 served on the staff of the Lutheran Hospital, aged 68 died, January 30, of cardiac decompensation

Thomas F Miller ♂ Lamar, Mo, Missouri Medical College, St Louis, 1899, past president and secretary of the Barton County Medical Society, served on the staffs of St Luke's and General hospitals, Kansas City, aged 64, died, January 10, of coronary occlusion

Joseph David Mitchell, Fort Smith Ark, College of Physicians and Surgeons, Little Rock, 1909 for many years associated with the Great Lakes Agency of the Indian Service at Lac du Flambeau, Wis aged 61, died, February 2, in the Veterans Administration Facility, Fayetteville, of nephritis

Willard Elizabeth Park, Dallas Texas Rush Medical College, Chicago, 1909 aged 70 died, February 1, in a local hospital of burns received in a fire which destroyed an apartment house in which she was visiting

J Lampton Price, Frankfort, Ky Bellevue Hospital Medical College New York, 1877, formerly health officer aged 87 died January 29 of arteriosclerosis

George I Reeves, Farnum Neb Ensworth Medical College St Joseph, Mo, 1902 aged 82 died January 23, in Burlington Iowa, of hypostatic pneumonia

George W Ringgold, Gould Ark, Arkansas Industrial University Medical Department Little Rock, 1886 member of the Arkansas Medical Society, aged 77, died January 25, of coronary occlusion

Edgar Allison Sears, Decatur Neb Drake University Medical Department Des Moines Iowa, 1888 member of the Nebraska State Medical Association, for two years county superintendent of schools, associated with the Indian Service for many years aged 83 died January 29, of heart disease

Solomon Thomas Shelly, Mulvane, Kan, Missouri Medical College, St Louis 1883 member of the Kansas Medical Society, served on the staff of the Atchison Topock and Santa Fe Railway Hospital, aged 86, died January 17, of hypostatic pneumonia

William E Waldrop, Parma Idaho Lonsville (Ky) Medical College 1903 member of the Idaho State Medical Association at one time county physician veteran of the Spanish American War for many years a member of the board of trustees of the school board formerly superintendent of the Idaho State Soldiers Home Hospital Boise aged 69 died January 27 in Boise of pneumonia and heart disease

Perry Trowbridge Walters, La Crosse, Wis University of Michigan Medical School Ann Arbor, 1933 member of the State Medical Society of Wisconsin secretary treasurer of the La Crosse County Medical Society on the staffs of the La Crosse Lutheran Hospital and the Gundersen Clinic medical examiner for drift board number 1 aged 38 died January 8 of carcinoma of the stomach with metastases

Joseph M Welch Sutton Neb Rush Medical College Chicago 1912 member of the Nebraska State Medical Association served as mayor of Sutton and on the school board on the staff of the Sutton Hospital aged 64 died January 26 of cardiovascular vascular disease

Robert Minor Wiley, Salem Va Medical College of Virginia Richmond 1895 member of the Medical Society of Virginia aged 72 died January 5 of paralysis agitans

Philip L Wise ♂ San Jose Calif University of Southern California College of Medicine Los Angeles, 1905 member of the Pacific Coast Oto Ophthalmological Society aged 62 died January 8 of heart disease

Katharine Woltemann, Delavan Ill Hahnemann Medical College and Hospital Chicago, 1904 aged 81, died January 12 of cerebral hemorrhage

William Purnell Yerger, Tallulah, La Memphis (Tenn) Hospital Medical College 1901 aged 65 died January 8

Stanley John Zolnowski ♂ Cleveland, St Louis University School of Medicine 1928 assistant in the department of pathology 1925 1926 and teaching fellow in the same department 1926 1927 at his alma mater aged 40 died January 6 of coronary thrombosis

DIED WHILE IN MILITARY SERVICE

Claude Edwin Hale Jr, Marshall Mich Vanderbilt University School of Medicine, Nashville Tenn 1917 member of the Michigan State Medical Society, served during World War I, captain in the medical corps Army of the United States, aged 46, died November 5 as the result of injuries received in a government vehicle in the Southwest Pacific area

Eli Silberstein, Brooklyn Regia Università degli Studi di Bologna Facoltà di Medicina e Chirurgia Italy 1940, was an intern at the Israel Zion Hospital first lieutenant in the medical corps of the Army of the United States called to active duty July 28 1942, aged 26, was shot and killed at Yuma, Ariz January 24

Varnum Cochran Southworth, Cambridge Md Detroit College of Medicine and Surgery, 1924, member of the Medical and Surgical Faculty of Maryland and the American Academy of Orthopaedic Surgeons was called to active duty as a lieutenant commander medical corps V (S) U S Naval Reserve aged 44 died February 9, in Hartford Conn of heart disease as the result of pneumonitis

HAZARD OF PARALDEHYDE ADMINISTRATION

To the Editor —In THE JOURNAL, March 6, page 783, appears a communication by Dr A H Miller in reference to my article on the "Hazard of Paraldehyde Administration," which appeared in the January 16 issue of THE JOURNAL.

I should like to repudiate all of Dr Miller's criticisms.

1 Dr Miller would propose a different caption for the paper, while he himself misquotes the original title.

2 Concerning the dosage for intravenous administration it is surprising to learn that an experienced anesthetist would employ a fixed, predetermined dose of 9 cc as the maximum intravenous dose. Any anesthetic agent administered intravenously should be injected at the proper rate until the desired effect is attained. Granted that 9 cc of paraldehyde intravenously is usually sufficient to produce anesthesia, there will be cases, as in the one described, in which this amount will be ineffective.

3 In his objection to the instillation by rectum of 35 cc of paraldehyde as excessive Dr Miller failed to mention that it was administered three times at six hour intervals. The amount actually given was 15 cc each time (a total of 45 cc and not 35 cc, as again misquoted).

4 The most objectionable criticism is the casual statement that paraldehyde is "an agent which, if not the safest of hypnotics, is certainly as safe as any." To repudiate this statement would require reiteration of the entire original paper, in which is given some of the history relative to fatalities following paraldehyde administration, as well as to reiterate the experimental evidence as reported in that article.

CHARLES BLURSTEIN, Captain, M C, A U S

TOXICITY OF HUMAN PLASMA

To the Editor —Our attention has been drawn to some inaccuracies in your editorial on Toxicity of Human Plasma (THE JOURNAL, Sept 19, 1942 p 206).

In the first place you refer to the A and B group specific substances as haptens. There is now considerable evidence to show that they are antigens and not haptens. In the second place the statement that 50 per cent of group A and 85 per cent of group B serums contain the corresponding agglutinin was qualified in our paper in the following way: "It should be mentioned here that the inhibition technic is not sufficiently sensitive to detect very small quantities of inhibiting substances" (*J Path & Bact* 54 92 [Jan] 1942). "It is evident that amounts of agglutinin too small to produce inhibition in vitro will yet produce a brisk response on injection. Although the inhibition test indicates that at least 50 per cent of group A and 85 per cent of group B persons have the corresponding agglutinin in their serum and plasma, it seems likely that the true percentages are higher" (*ibid* p 101). Thirdly, the terms serum agglutinin and isoagglutinin have been confused, it was isoagglutinin and not agglutinin titers which we estimated after pooling plasma from A and B donors. We made no estimation of residual agglutinin after pooling in view of the presence of free anti A and anti B isoagglutinins probably only small amounts of A and B agglutinin were present.

MEDICOLEGAL ABSTRACTS

Insanity Criteria of Criminal Responsibility—The defendant was convicted and sentenced to ten years' imprisonment for first degree robbery and appealed to the Supreme Court of Missouri. He admitted that the state's evidence was sufficient to support the conviction but on appeal contended that he was not capable of the intent required to be guilty of the offense in that he was mentally deficient and at certain periods, especially when he drank, he had not the capacity to distinguish right from wrong conduct.

There can be no doubt, said the Supreme Court of Missouri, but that legal mental capacity to commit a crime is an essential prerequisite to responsibility and a person cannot be legally punished for an act committed by him while insane, although the act would constitute a crime if done by a sane person. While the law recognizes the existence of many forms and degrees of insanity, mental incapacity excusing the commission of a crime must be such that the defendant is unable to distinguish right from wrong at the time of the commission of the offense, and the burden is on the defendant to prove the facts from which a jury may reasonably infer the fact of legal mental incapacity. Morosity, mere weakness of intellect or subnormal mental capacity, is not in and of itself such insanity or mental incapacity as constitutes an excuse or defense to a crime. The total effect of the defendant's evidence in this case the court pointed out, was not that he was insane but that he was a person of subnormal mental ability and capacity. This evidence does not prove insanity in the sense required by law. Broadly speaking voluntary intoxication, regardless of the person's intellect, is not a defense to a criminal charge and has no bearing on it except in certain instances not involved in the present case. The defendant's argument, the court continued, was merely of the commonly known phenomenon that liquor does affect one, at least to the extent that he does not act and conduct himself as he normally does and would if he were not drinking. The defendant's experiences and reactions in this respect, however, presented nothing new or unusual, certainly not insanity or even delirium tremens induced by intoxication.

The defendant did not claim to have been intoxicated to the extent that the liquor totally deprived him of his reason or that he was insane but argued that because he was a person of subnormal mentality and had been drinking, the combination of the two "laid a foundation" for the proof and defense of insanity of which he was deprived by the adverse ruling of the trial court on certain evidence offered. The trouble with this position, said the court, was that the only witness qualified to speak on the subject of the sanity of the defendant, a psychiatrist, stated that the defendant was sane when he examined him two years prior to the commission of the offense and that he had no opinion as to his mental condition after that time because he had not subsequently examined him. The evidence given by the lay witnesses to the effect that the defendant did not act or conduct himself as usual when he was drinking, that he kept his hands in his pockets and asked people for money when he was drinking were not such facts and circumstances from which they or any one else could draw the inference or express the opinion that he was insane or so lacking in mental capacity as to be excused from the charge of robbery if the jury believed him to be guilty under all the evidence.

The judgment of conviction was therefore affirmed.—*State v. Pugh, 163 S. W. (2d) 785 (Mo., 1942)*

CENTRAL SOCIETY FOR CLINICAL
RESEARCH*Fifteenth Annual Meeting held in Chicago Nov 6 and 7 1942*The President, DR ARLIE R BARNES, Mayo Clinic, Rochester,
Minn., Presiding*(Continued from page 1176)***"Three to One" Modified Protamine Zinc Insulin**

DRS CYRIL M MACBRYDE and HAROLD K ROBERTS St Louis The protamine zinc insulin now in use is not ideal for maintenance of control in many diabetic patients. The need for a type of insulin effective for at least twenty-four hours, but with sufficient rapid activity to prevent postprandial hyperglycemia, is widely recognized. In the past two and one-half years among 154 well controlled diabetic patients whom we have followed, 35 per cent required combined therapy with protamine zinc insulin and a separate morning injection of regular insulin. Nearly all patients needing over 40 units daily required combined therapy for good control. The most widely useful ratio consists of three parts of protamine zinc insulin to one of regular insulin. The combined method of treatment is objectionable, however, because it is a compromise, partly nullifying the advantages of the slow acting protamine zinc insulin. Two injections are still required, and the patient is obliged to manipulate two very different forms of insulin, multiplying the possibilities of error.

Comparative twenty-four hour blood sugar curves on 18 diabetic patients under controlled conditions showed great similarity between those obtained with protamine zinc insulin as compared with histone zinc insulin. Diabetic control was better with protamine zinc insulin, while histone zinc insulin failed to exhibit the desired more prompt action. Comparative curves with clear (acid, or soluble) protamine zinc insulin on 11 patients revealed better control with the market turbid protamine zinc insulin, while the clear insulin failed to give evidence of more rapid initial activity. Studies with globin insulin and other insulin modifications have been disappointing.

The most promising field proved to be mixtures of protamine zinc insulin and regular insulin. When protamine zinc insulin and regular insulin are mixed in the proportions employed when separately injected in the combined method of therapy, all or practically all of the insulin is precipitated. By combining equal parts of protamine zinc insulin and regular insulin, and adjusting the pH to 7.2, however, it is possible to prepare a form of modified protamine zinc insulin which has the activity of three parts of protamine zinc insulin to one part of regular insulin, which is the proportion found most useful for the large majority of our patients. This special 3:1 modified protamine zinc insulin, when compared with protamine zinc insulin in 11 patients, gave better diabetic control with lower blood sugars during the day and equally good control of the night and fasting sugar levels. Comparison of 3:1 insulin with combined protamine zinc insulin and regular insulin therapy revealed somewhat better control with the 3:1 insulin than with the two separate injections. Six patients under controlled conditions showed comparatively little blood sugar fluctuations throughout the twenty-four hours, although in 4 cases the single dose administered was 70 units or over. Thus it would seem that a single injection of 3:1 modified protamine zinc insulin can take the place of market protamine zinc insulin in the regulation of mild diabetes when supplementary injections of regular insulin are not required and can also be substituted for the two separate injections required by most diabetic patients needing more than 40 units of insulin daily.

DISCUSSION

DR R M WILDER, Rochester, Minn. What criteria were used for adjusting the dosage day by day of the mixed insulin? Is the morning urine tested and a lower dose given when the morning urine is sugar free, or is some other time of testing better for determining whether the dose is satisfactory or not? We have also been giving mixed insulins for some time, not

a fixed preparation such as Dr MacBryde is using but shifting the preparation, depending on the shifting daily requirements. Some people seem to do better with more protamine zinc insulin and less regular insulin, some, but not all, do well with preparations like those Dr MacBryde has found satisfactory. The patient tests the urine twice daily, and we use the result of the morning test as the criterion of whether or not the protamine component is as high as we want it to be. The afternoon test tells whether the regular component should be increased or decreased. I would like to know, using fixed proportions, how Dr MacBryde knows whether to increase or decrease the dose of the mixture. After he determines the dose in the hospital what criteria will the patient use at home?

DR CYRIL M MACBRYDE, St Louis. Most of our studies have been done in the hospital on carefully controlled patients, with diets accurately weighed, all urines collected for quantitative sugar determinations, and blood sugars frequently determined. We have some patients now controlled with 3:1 insulin who are coming to the clinic or are seen as office patients. Our criteria for control are the same as those we have used in treating patients with protamine zinc insulin alone or with the combined treatment, using separate injections each morning of protamine zinc insulin and regular insulin. If the fasting blood sugar is too low and there is no glycosuria during the night or if there are any indications of hypoglycemia during the night or in the early morning, the patient may be getting too much protamine zinc insulin effect. If the blood sugar is too high at night or glycosuria occurs, we know that the protamine zinc insulin effect is not sufficient. On the other hand, the blood sugar two hours after breakfast and the glycosuria during the morning tell us whether we are getting enough of the rapid insulin effect. With 3:1 insulin we are encouraged by the fact that the controls in these two periods tend to go together. We are obtaining relatively flat curves throughout the twenty-four hours. Previously the night period reflected chiefly the effect of protamine zinc insulin, while the period after breakfast showed the response to the separate injections of regular insulin. With the new 3:1 modified protamine zinc insulin, giving 75 per cent prolonged effect and 25 per cent rapid effect, we have accomplished in most of our cases much better control throughout the twenty-four hours. I am much opposed to the use of extemporaneous mixtures of protamine zinc insulin and regular insulin. In the first place the rapid insulin effect is not obtained to any perceptible degree unless an amount of regular insulin at least equal to the amount of protamine zinc insulin is used. If the pH is not readjusted to 7.2 the material injected is more acid than the tissue fluid and thus introduces further variation in the rate of absorption. The great majority of patients should not and cannot be trusted to mix various forms of insulin for themselves. Most physicians are much too busy to worry with all the intricate details of numerous variable mixtures. The treatment of diabetes is complicated enough without making it more so. If the 3:1 insulin we have described can be substituted for the two separate injections previously needed for a large percentage of diabetic patients, it will simplify the problems both of patient and of physician.

**Mechanism of the Action of X-Ray Therapy
on Infection**

DRS J DEWEY BISGARD and HOWARD B HUNT Omaha. In a series of rabbits the peritoneal cavity was inoculated with a culture of hemolytic colon bacillus establishing a constant minimal lethal dose. Two slants of a forty-eight hour culture invariably caused death of the animals within eight hours after inoculation. Sulfanilamide and sulfathiazole given in large therapeutic doses either by stomach intravenously, subcutaneously or by implantation into the peritoneal cavity preceding or at the time of inoculation had no influence on the result of the inoculation. However, in a group of animals receiving 100 roentgens over the abdomen at periods varying from twenty-four to ninety-six hours before inoculation there were approximately 50 per cent survivals. Sixty per cent of the animals irradiated forty-eight hours before inoculation survived. From this survival peak there was a rapid decline so that there were

no survivals in those inoculated ninety-six hours after irradiation. All control animals inoculated at the same time died.

Because this culture produced such a rapidly fatal result it was decided to determine the effect of inoculating the peritoneal cavity with the killed culture. It was found that the killed culture was equally fatal and that preinoculation x-ray irradiation gave the same results as previously enumerated. It appeared therefore that the animals were not dying from a fatal infection but rather from a fatal toxin and that irradiation caused the tissues to produce some factor capable of neutralizing the toxins.

In a third series blood was drawn from animals forty-eight hours after irradiation and the serum mixed with live cultures in one group and with killed cultures in another and these respectively were injected into the peritoneal cavities of stock rabbits. From 50 to 60 per cent of animals so treated survived. Thus it appears that the neutralizing effect of irradiation is not a local one but is the result of an antitoxic substance liberated into the blood stream. Irradiation gave about the same degree of protection to animals inoculated with a lethal dose of diphtheria toxin.

From these studies and from related ones which are still in progress it is our belief that the insult of irradiation to tissues causes them to liberate nonspecific antitoxic substances and that these substances are present in the blood stream and peritoneal fluid.

Comparative Study of Pathogenesis and Pathology of Pneumonitis in Infancy

DR. JOHN M. ADAMS, Minneapolis. The pathogenesis and pathology of nine different forms of pneumonitis in infancy have been considered separately and comparatively, and only the distinctive pathologic anatomic features have been related to the etiology and development of each entity. Three cases of sudden death due to pneumonitis have been presented. The study was conducted according to this outline:

- 1 Aspiration pneumonia (lipoid pneumonitis)
- 2 Tuberculosis (first infection type of pneumonitis)
- 3 Eosinophilic pneumonitis (Loeffler's syndrome)
- 4 Interstitial pneumonitis (whooping cough, measles and so on)
- 5 Primary virus pneumonitis
- 6 Secondary virus pneumonitis (Goodpasture)
- 7 Primary pyogenic pneumonia
- 8 Secondary pyogenic pneumonia
- 9 Syphilitic pneumonitis (pneumonitis alba)

Fat laden macrophages and foreign body giant cells set apart the pneumonias resulting from aspiration. In tuberculosis the epithelioid cell and enlarged mediastinal nodes characterize the entity. Widespread pulmonary infiltration of the eosinophilic cell, coinciding with the high blood eosinophilia, is assumed for Loeffler's pneumonitis since there has been no opportunity to study autopsy specimens. The blood eosinophils are larger than normal, with unusually large granules, which are fewer in number.

The thickening of the various constituents of the pulmonary system seen in interstitial pneumonitis is distinctive. The peribronchitis with small round cell infiltration adds to the picture. The features of primary virus pneumonitis are similar, with ulceration and proliferation of epithelial lining membranes plus the presence of cytoplasmic inclusion bodies in the epithelial cells. The secondary form has intranuclear inclusions in the epithelial structures as its specific differentiating feature.

The presence of leukocytes and specific bacteria with abscess formation and empyema distinguish the pyogenic pneumonitis. Syphilitic pneumonia is characterized pathologically by the extreme hyperplasia of the fibrous elements and the presence of *Treponema pallidum*.

From an immunologic point of view the immature lung of infancy is a most vulnerable organ, being readily susceptible to nearly all forms of pneumonia. Primary agents such as the pyogenic bacteria and pneumotropic viruses may produce fulminating disease and even sudden death.

DISCUSSION

DR. W. J. BROWN, Omaha. A few months ago inclusion body hemorrhage developed in a child who had been delivered by elective cesarean section; the amniotic membranes had not been ruptured. There was some curiosity as to this infection at birth in a child with no lung defect. The mother was apparently normal. An investigation was then begun of the vaginal epithelium of apparently normal women. To our surprise, various forms of inclusion body intracellular and extracellular organisms were present in 22 out of 25 normal women. We have raised the question at the University of Nebraska whether these inclusion bodies have anything to do with virus or are large toxic granules. In children we find these inclusion bodies in osteomyelitis and other infections in which virus is not usually encountered.

DR. JOHN M. ADAMS, Minneapolis. In our babies in two epidemics we have had no conjunctivitis. Inclusion hemorrhage begins from the fifth to the tenth day of life. The average age at onset of pneumonitis was 7 ± weeks. We have observed this disease in babies as old as 6 or 7 months particularly prematurely born babies after they have passed the period of immaturity; they still are apparently more susceptible to this disease. I cannot say how significant the finding of inclusions is in the sputum. We are at present studying the sputum of a good many patients with other diseases. We have not observed primary virus pneumonitis outside of small infants. Broadhurst in New York has found inclusion bodies in the sputum of adults nurses and doctors suffering from upper respiratory infection.

Treatment of Acute Bacillary Dysentery (Flexner) with Sulfaguanidine and Succinylsulfathiazole

DRS. CHARLES I. SMITH, SYLVESTER F. GOLD and MORIS B. FINKELSTEIN, Ithaca, Mich. During an outbreak of acute diarrhea 86 patients were studied. From the stools of 25 *Shigella* paratyphenteric (variety Flexner) organisms were cultured. Thirteen patients were treated with sulfaguanidine and of these, 9 had positive stool cultures; 25 patients were treated with succinylsulfathiazole and 14 of these had positive stool cultures. With few exceptions the dosage of sulfaguanidine was 0.1 Gm. per kilogram of body weight initially, and a maintenance dose of one half of this was given every four hours. The dosage of succinylsulfathiazole was 0.25 Gm. per kilogram of body weight initially and 0.25 Gm. per kilogram daily divided into six equal portions given every four hours.

The results of this study indicate that the new sulfonamide compound succinylsulfathiazole has no definite advantage over sulfaguanidine in its effect on fever, diarrhea and time required for stool cultures to become consistently negative. Although both drugs were administered in the doses recommended by other investigators a recurrence of positive stool cultures was observed once after each drug. Five fatalities occurred; three were of untreated patients, 1 was treated with sulfaguanidine and the other with succinylsulfathiazole.

Determinations of the blood concentrations revealed that sulfaguanidine was absorbed to a greater extent than succinylsulfathiazole. A concentration of 16.6 mg. of sulfaguanidine per hundred cubic centimeters following the administration of 27 Gm. of this drug in three days was observed in 1 case. In no instance did the blood concentration of free sulfathiazole exceed 1.39 mg. per hundred cubic centimeters or the total succinylsulfathiazole 1.45 mg. per hundred cubic centimeters. No significant changes were observed in hemoglobin and white blood cell counts following the use of either drug.

The effect of the administration of a second course of these drugs on twenty patients was investigated. 11 received sulfaguanidine and nine succinylsulfathiazole. Three of the patients given the second course of sulfaguanidine manifested definite signs of toxicity, but no reactions followed the readministration of succinylsulfathiazole.

We believe that the two drugs are equally effective in the treatment of these cases, but because succinylsulfathiazole is potentially less toxic it is the drug of choice. Repeated stool cultures to detect carrier states following sulfonamide therapy of acute bacillary dysentery (Flexner) are necessary.

DISCUSSION

DR G F KEMPF, Indianapolis I should like to know what advantage either of these drugs has over sulfathiazole in this disease

DR M A BLANKENHORN, Cincinnati I think it is extremely difficult to demonstrate the value of a drug in a disease as variable as dysentery and, moreover, to compare two drugs and say which is better I would understand this epidemic better if Dr Smyth would say something of the circumstances of the outbreak, particularly the day of the disease on which the patient was put on treatment He was fortunate to have the epidemic in his institution, where he could get a good idea of its intensity, rather than in a general hospital, where only an occasional case is seen I have seen a rather generous sprinkling of cases and I am undecided about the value of either of these drugs in dysentery I think the mortality rates cited are rather high I think 2, 3 or 4 per cent is a fair estimate of the mortality rate Will he tell us more of the circumstances of the epidemic and state the day of the disease in which treatment was started?

DR H MARVIN POLLARD, Ann Arbor, Mich I should like to ask Dr Smyth if he found any organism other than Flexner's dysentery bacillus in the stool cultured, and if so whether succinylsulfathiazole had any effect on them During the past several months I have treated 12 cases of chronic ulcerative colitis with succinylsulfathiazole Four of these patients had a prompt drop in temperature and the others had a gradual fall of temperature In general the stools became less frequent, and blood disappeared from the stools completely in a period of one to three weeks One patient has received up to 1,200 Gm and none of these patients have had any type of reaction that could be directly attributed to the drug In general, I feel that it is a safe and valuable adjunct to the other forms of treatment necessary for these individuals

DR CHARLEY J SMYTH, Eloise, Mich We have had no experience with sulfathiazole in the treatment of dysentery Yarnet and his associates in Connecticut reported more rapid clinical recoveries in cases with Sonne dysentery treated with sulfathiazole but pointed out that there was a significant prolongation of the time required before the rectal cultures became consistently negative as compared with a control group From our study of these relatively few cases we feel that, if succinylsulfathiazole is given in the amounts we have indicated, positive stool cultures can be controlled effectively and the course of the disease, as judged by fever and diarrhea, shortened The epidemic that we studied occurred in two wards of a mental and general hospital with a total population of 9,000 All patients suspected of having dysentery were segregated at once in an isolation ward There were many chronically ill and debilitated patients, and perhaps the high death rate may be due to that fact No other pathogenic organisms of any significance were recovered Although the final decision regarding the value of succinylsulfathiazole will be based on further clinical use, the results of this comparative study indicate that it provides a definite advance in the treatment of this important enteric disease

The Effect of Arsenic (Solution of Potassium Arsenite) on Erythropoiesis

DR LOUIS R LIMARZI, Chicago Following the oral administration of arsenic in relapsing cases of pernicious anemia the bone marrow shows severe toxic and destructive changes in the megaloblastic tissue consisting of various phases of caryorrhexis A reticulocytosis as high as 18 per cent is observed peripherally in some cases without improvement in the anemia The icteric index is not increased If liver extract is administered to such a patient there is a normoblastic stimulation with an improvement in the anemia The caryorrhetic fragments of the megaloblasts can still be observed for four or five days

The oral administration of arsenic to normal controls and to persons with sickle cell anemia erythroblastosis, hypochromic anemia, cirrhosis of the liver, carcinoma of the stomach and polycythemia vera in which the bone marrow consists of

moderate to severe erythroid hyperplasia and immaturity produces no significant degenerative changes in the normoblasts In spherocytic jaundice and in 1 case of refractory anemia with macrocytosis following the administration of arsenic, caryorrhexis in the polychromatic and orthochromatic normoblasts in the bone marrow is a conspicuous feature

In none of the bone marrows is the pronormoblast affected by arsenic

It is concluded that (1) the megaloblast in the bone marrow of relapsing cases of pernicious anemia is arsenic sensitive and the pronormoblast seen in normal marrow and in the bone marrow of most cases of anemia with an erythroid immaturity is arsenic resistant (2) the 'liver principle' can exert its physiologic effect on the bone marrow in pernicious anemia in the presence of a caryorrhetic megaloblastic tissue which presumably is in a poorly functional condition due to the toxic effect of arsenic and (3) the action of the hemopoietic principle is probably to effect the elimination (maturation) and suppression of the megaloblasts in the bone marrow It is still not clear as to how the liver extract effects a stimulation of the normoblastic tissue It is clear that arsenic has no such effect

Effect of Breathing 80 to 100 Per Cent Oxygen on the Erythrocyte Equilibrium in Patients with Sickle Cell Anemia

DR EDWARD H REINHARD, DR CARL V MOORE, R DUBACH, PH D, and DR LEO J WADE, St Louis The effect of prolonged administration of 80 to 100 per cent oxygen to patients with sickle cell anemia has been observed The study was undertaken to determine whether the oxygen tension of arterial blood could be raised sufficiently to decrease the intravascular sickling of red cells It was thought that this might accomplish (1) a reduction in the rate of hemolysis with consequent lessening of the degree of anemia and (2) relief of pain during sickle cell crises Observations have been made on 3 patients at six different times After control periods of four to eight days the subjects were fitted with a Boothby-Lovelace-Bulbuhani mask and given pure oxygen without intermission for eight to twenty days Red cell counts, hemoglobin levels and reticulocytes were estimated daily Determinations of serum iron and of oxygen content and capacity of both arterial and venous blood were made every four days Excretion of urobilin in urine and stool was measured as an index of the rate of hemoglobin destruction (method of C J Watson) The percentage of sickled cells in arterial and venous blood was determined regularly (I J Sherman's method) Alveolar oxygen content was measured on several occasions

Administration of nearly 100 per cent oxygen to these patients when they were having abdominal or muscular pain did not regularly give them relief However, within a short time after the flow of oxygen was started the percentage of sickled cells in both venous and arterial blood decreased definitely, often from over 40 per cent to less than 20 per cent in the venous circulation This change persisted as long as pure oxygen was breathed The oxygen content of the arterial blood was increased so that it equaled or exceeded the oxygen capacity No consistent change occurred in urobilin excretion, however, to indicate that the rate of hemolysis had been materially altered The most dramatic results of prolonged oxygen administration were (1) a fall in reticulocytes which usually began on the fourth to sixth days and which lowered the level from the initial 20 to 30 per cent to as low as 1 per cent, and (2) a fall in the erythrocyte count, which usually began on the sixth to eighth days and was as great as 0.5 to 1.5 million cells After oxygen was discontinued, the reticulocytes began to increase and reached a peak of occasionally more than 50 per cent on the fifth to eighth days A shower of normoblasts appeared concomitant with the reticulocytosis At the same time the red cell levels began to increase and the rise continued until the preoxygen level had been attained These results are interpreted as indicating that the administration of nearly 100 per cent oxygen depresses erythropoiesis, an effect which might be the physiologic antithesis of the erythroid stimulation produced by low oxygen tensions It is suggested that this result has not been noted in previous studies when high concentrations

oxygen were given to normal persons and to individuals with polycythemia because the length of red cell life is so great that the decreased rate of erythrocytogenesis would not be evident for long periods. Patients with sickle cell anemia show the effect more quickly because their reticulocyte level is elevated and their rate of red cell destruction accelerated.

No distinct toxic manifestations of the oxygen administration were noted except for inflammation and congestion of the mucous membranes of the upper respiratory passages. After oxygen was discontinued 2 of the 3 patients became nauseated and had headaches for twenty-four to forty eight hours.

DISCUSSION

DR C. J. WATSON, Minneapolis: The alteration of the reticulocytes following the administration of oxygen is interesting. I think that the hypothesis offered is the only one that is tenable. It would be interesting to see what would happen to the reticulocyte count in hemolytic jaundice if oxygen should be given. I was most interested in the effect of oxygen and the way these patients tolerate oxygen. From the work Payne did with dogs I would not have expected patients to tolerate oxygen for so long. Payne found that in the dog several hours of 100 per cent oxygen often caused severe changes and after twenty-four hours death with contraction of the spleen commonly ensued. As the percentage of oxygen decreased the animals tolerated it better, 80 per cent oxygen could be tolerated for a long period without untoward effect.

DR EDWARD H. REINHARD, St. Louis: We have not studied the effect of high oxygen tensions on the blood of patients with hemolytic anemia. We did wonder if the inhibition of oxygen by patients with pernicious anemia might prevent the usual reticulocyte response to liver therapy. This was tried on 1 such patient with equivocal results. We are planning to repeat these investigations on patients with various types of anemia. As to the toleration of oxygen by our patients we have no completely satisfactory explanation as to why they developed no serious toxic manifestations. Our patients wore oronasal masks at night and nasal masks during the day. It has been shown that, when a person wearing a nasal mask talks or eats, the oxygen concentration of the inspired air decreases definitely. Undoubtedly this was a factor in preventing the development of oxygen intoxication.

The Response to Heparin: A Test of the Clotting Mechanism

DRS. GEZA DE TAKATS and N. C. GILBERT, Chicago: Following the intravenous injection of a 10 mg. dose of heparin, coagulation times have been determined at ten minute intervals. One hundred and fifty-four tests were made on 67 patients. A normal response was plotted from an average of fifty curves. A group of hypercoagulable patients were found who showed varying amounts of resistance to heparin. They were patients in the early postoperative period, patients examined within a few days after an intravascular thrombosis and patients suffering from Buerger's disease. It was found that both digitalis and epinephrine have a depressing effect on heparin response. Conversely, a group of hypercoagulable patients were encountered who showed clinical signs and symptoms of sensitization together with an exaggerated response to heparin. They may or may not have received heparin previously.

Compounds containing sulfur seemed to augment the action of heparin. The action of heparin on the coagulation time is biphasic and the relationship of the curves to one another indicates that any drug which exaggerates the first curve will tend to depress the second.

Based on these observations, it is suggested that no patient be heparinized unless a heparin curve is previously determined. The best and simplest method of administration is the intermittent injection of 50 mg. of heparin every three to four hours, with an adequate check on coagulation times. The length of administration need not exceed three days, after which dicumarol can be started. While heparin is more expensive and needs intravenous injections its dosage is easily controlled, whereas dicumarol is given orally but requires daily prothrombin levels, which are unobtainable except in large hospitals.

DISCUSSION

DR L. N. KATZ, Chicago: May I ask if observations on the heparin reaction in patients with Buerger's disease have been made to see whether the decreased sensitivity preceded or followed its onset?

DR OWEN O. MERRILL, Madison, Wis.: Some people are hypersensitive to dicumarol and some are hypersensitive, but the hypercoagulable are more numerous. I am not certain of the method employed in determining the coagulation time in this series. I presume, because of the short coagulation times reported, that it was done by the capillary method. The coagulation time of the so-called hypersensitive individuals was less than a minute shorter than that of the normal reactors. This difference would scarcely seem to be significant. If the capillary coagulation time is used, one must admit that it is relatively crude. I favor the determination of the coagulation time on venous blood. Although there are plenty of fallacies in the method of Lee and White, it appears that they are less numerous than when capillary blood is used. The importance of determining the coagulation time frequently when using heparin is well recognized. It is my practice for at least the first day of heparin administration to determine the coagulation time every few hours. It is now the usual practice for a patient who has thrombosis already developed to administer heparin intravenously for the prompt effect because with dicumarol there is a latent period of about twenty-four hours, and this is true whether the preparation is administered intravenously or orally. At the time of the heparin administration we begin oral administration of dicumarol. We can tell when the latter substance becomes active because the prothrombin time which is unaffected by heparin will be prolonged. Then the heparin is omitted and dicumarol therapy alone is continued.

DR AUGUST QUICK, Milwaukee: This paper brings out the fact that heparin itself is not an anticoagulant but becomes so only when it reacts with something in the blood which presumably is albumin but which is probably best called albumin X. It is this albumin X which forms the true anticoagulant with heparin. It appears probable that the serum factor may vary, which accounts for the hypocoagulability and hypercoagulability of heparin in various bloods. I agree with Dr. Merrill's remarks on the coagulation time. A committee should be formed to standardize the determination of the coagulation time. The coagulation time determined according to the procedure of Lee and White yields much more satisfactory and uniform results if the temperature is kept constant (37° C). It has been observed that hemophilic blood which clots in two or three hours at 37° C may at room temperature require twenty-four hours for clotting.

DR FRANK H. BETHGEL, Ann Arbor, Mich.: I should like to ask Dr. de Takats if he has studied the prothrombin time in relation to reactions.

DR GEZA DE TAKATS, Chicago: If one produces a thrombosis in the lower extremity with a sclerosing solution there is usually a flattening of the heparin curve. A patient with deep femoral thrombosis presents a flattening of the heparin curve which disappears after ligation of the vein. It is quite probable that the flat curves are the result of the clot. On the other hand, it is also true that one can pick up patients with a flat postoperative curve, and this is particularly observed in the gynecologic service. We feel that if the patient has a flat heparin curve after the fourth postoperative day, thrombosis is likely. We had 5 such patients, 1 of whom developed embolism and 4 postoperative thrombosis. We now use dicumarol after two days of heparin. The action of the latter drug is prolonged. We are perfectly aware that Lee and White's method is the standard method for blood coagulation. We still believe, however, that the capillary coagulation time is useful. We were anxious to devise a method that could be run by nurses or interns in any hospital. We get errors with the capillary method, but the percentage of error is the same during the test. Dr. Quick mentioned that heparin itself is not an anticoagulant, that it is only an activator. Heparin does not seem to do anything to the prothrombin time. Our difficulty with the administration of dicumarol is that unless the prothrombin time is determined by skilled technicians dicumarol is dangerous. One dislikes to use dicumarol because of the difficulty of adequate control.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

New Type of Relaxing Incision—A new relaxing incision which combines the advantages of primary closure by a cutaneous graft and eliminates the necessity of making a separate wound to obtain closure is described by Harkins. It consists of a dermatome graft which is left attached at one end and reflected back. The incision is then made in the donor area or bed of the graft and the flap is turned down again to cover the raw area made by the incision. This method is especially applicable to wounds of the extremities from which large superficial tumors or scars are excised.

Plasma Protein Variation in Surgical Patients—In 215 consecutive surgical patients admitted to the Hospital for Joint Diseases Casten and his collaborators tried to determine the incidence of hypoproteinemia associated with operations and its relationship to various procedures, the factors which influence changes in plasma proteins, the relationship between hepatic disorders and hypoproteinemia and ways of preventing and treating hypoproteinemia. Following the operative procedure, plasma proteins and hematocrit were determined immediately and thereafter every twelve to twenty-four hours until the patient recovered. A significant decline in the plasma protein level was observed in 148 or 68.9 per cent of the patients. The decline was more common after operations on the stomach and intestine, the biliary tract, the spine and large joints and for toxic thyroid disorders. Among the many direct factors which influenced the extent and duration of the diminished protein concentration were blood loss, shock and anesthesia, while the indirect causes were the nutritional status of the patient, extent of the protein reserves and the adequacy of hepatic function. Depreciation because of blood loss and shock was usually of short duration and readily amenable to therapy, but when the protein reserves were exhausted or hepatic function was disturbed the depletion was prolonged and frequently response to treatment was irregular. As the hepatic function is known to be disturbed frequently in certain surgical conditions of an extrahepatic nature, the hepatic function of such patients should be tested routinely and the data should guide subsequent therapy. In the operations known to be almost constantly associated with much loss of protein, the estimated loss should be replaced during operation by blood or plasma transfusions. If protein reserves are thought to be exhausted, the operation should be postponed until the reserves are restored by dietary therapy high in amino acids or the feeding of amino acids if the dietary cannot be given. Plasma is a readily available and potent source of protein and often proves efficacious when dietary therapy fails.

Intrathoracic Neuroblastoma—Lee and Ritter report the case of a 5-month-old infant who had puzzling symptoms and was finally diagnosed as having intrathoracic neuroblastoma as the result of aspiration biopsy under fluoroscopic guidance. Though the infant's condition was fair at the close of operation, he died about three and a half hours later. At necropsy the cavity on the right side of the chest contained about 75 cc of dark red blood. The lung on the right side was fully collapsed and the one on the left was well aerated. The cause of death was probably hemothorax and associated shock. The diagnosis from a pathologic examination of the tumor was an atypical neurocytoma; there were hemorrhagic areas in the spleen, the lung on the right side was atelectatic and the one on the left

was normal, and the adrenals, kidneys and sternum were apparently normal. Early recognition of these tumors and prompt surgical and roentgen treatment will materially enhance the prognosis.

Hypertension After Metrazol Shock Therapy—Menninger reports an instance in which hypertension has persisted for four years since metrazol shock treatment. The mechanism of the cardiovascular dynamics is not clear. The author believes that the anxiety and the fear connected with such treatment were as important in producing the hypertension as was the drug or the convulsions. The psychiatric picture did not change at the time either as a result of therapy or with the onset of hypertension, but it did twelve months later after psychotherapy. The blood pressure has remained between 175 and 180 systolic and 115 and 125 diastolic as compared to the initial pressure before metrazol shock therapy was begun four years ago, of 110 systolic and 80 diastolic.

Communal Feeding—The communal feeding of some 10,000 Royal Ordnance Factory workers (mostly girls) resident at hostels adjacent to the factories according to Gimson, seems to improve notably the health of these residents. This improvement can be attributed in part at least to the manner and method of the feeding arrangements. In general the types of food necessary for health are well appreciated and these are supplied to the limit to which they are procurable. The catering management is in good hands, but more precise direction in the preparation of some particular foodstuffs is desirable and would be welcomed. The communal meal is a practical and economic arrangement so far as Royal Ordnance Factory workers living in hostels are concerned.

Diphtheria in Northern Palestine—An outbreak of diphtheria mainly confined to certain units with one unit showing a heavy infection but with cases being widespread throughout all troop units in the area is reported by Cameron. In the last war swabbing of contacts and isolation of carriers were sufficient to control most outbreaks. The outbreak occurred in the same theater of war as in 1914-1918. The frequent occurrence of acute cutaneous and nasal diphtheria alongside the faucial type was a further point demanding consideration. All suspected patients were hospitalized and nasal and faucial swabbing was enlisted in the search for carriers. In investigating the native population it was found that Jewish children (who at the time had crusted and discharging noses) are the usual sufferers from diphtheria and that the British troops were brought into closer association with the Jews than with the Arabs. The most probable origin would appear to be the children of the country. In both children and troops the nose was the commonest source of the organism. Preventive measures in the army must be directed toward immunization of troops. The clearance of carriers among the civil population is a local government problem. After six months of continuous cases of diphtheria the outbreak was successfully ended by immunizing all personnel of the unit. Since then, ten months no further cases have been reported although the unit has continued to stay in the area in which the infection was presumed to have arisen. In contrast, in another unit for which immunization was not instituted sporadic cases have continued. The same observation applies to several other units similarly treated. Isolation and swabbing alone appear not to answer the problem completely—a further justification for immunization of all personnel.

Book Notices

The 1942 Year Book of Industrial and Orthopedic Surgery. Edited by Charles F. Painter M.D. Orthopedic Surgeon to the Massachusetts Women's Hospital and Beth Israel Hospital Boston. Cloth. Price, \$3. Pp. 424 with 302 illustrations. Chicago: Year Book Publishers Incorporated 1942.

This is the third review of this series, which is rapidly proving its worth. The compiler is well qualified for the task of selecting articles, authors and subjects. He has mature judgment. The subjects chosen are representative and well balanced. The authors are well recognized in their special fields. The general trend of the papers reviewed is toward traumatic, industrial, medicolegal and military subjects. The abstracts are well done, separating the wheat from the chaff and preserving the meat of the articles. The illustrations are reproduced satisfactorily. In this small volume one can obtain a bird's eye view of the progress and trend of orthopedic and traumatic surgery. The military application is emphasized. The intervertebral disk syndrome is discussed briefly. Some of the principal subjects covered are low back pain, the disk syndrome, arthritis, the Kenny treatment for infantile paralysis, the sulfonamides in orthopedic practice, osteomyelitis, burns, the scalenus syndrome, fractures of the hip, patella, humerus and elbow, wounds, amputations, soft tissue tumors, and tuberculosis of bones and joints. Operative procedures are described as well as advances in diagnosis. On the whole, the book is of the type eagerly awaited by the busy practitioner, who in this instance will not be disappointed.

Human Embryology. By Joseph Krafka Jr. M.D. Ph.D., Professor of Microscopic Anatomy University of Georgia School of Medicine Augusta Medical Students Series. Cloth. Price \$4.75. Pp. 395 with 222 illustrations. New York & London: Paul B. Hoeber Inc., 1942.

There is a widespread feeling in this country that the major ill of the medical curriculum is the failure of medical teachers to separate the important from the less important. In all the medical sciences—and arts—the rate of increase of new knowledge is ever increasing. This, with the addition of new sciences to the medical family, has made our present curriculum a monstrosity in which the student, armed with an array of encyclopedic textbooks, is required to learn much of the premedical and preclinical sciences and to spend an increasing period in postgraduate instruction. To remedy this condition various solutions are being considered by many of our leading medical schools. One of the results of this soul searching on the part of medical teachers is the appearance of a few smaller textbooks designed for students. Most, but not all, teachers feel that there is a great need for such textbooks but do not want quiz compends. The preparation of abbreviated books is difficult. The author or authors must possess a comprehensive knowledge of the field, including its controversies on unsettled questions. Perhaps the greatest danger in producing the shorter textbooks is the tendency to insert a short dogmatic sentence to cover a broad controversial subject.

With regard to this book, one cannot agree that an adequate consideration of experimental embryology is unnecessary. The discussion of heredity is much too brief for medical students. Some of the data usually presented in the laboratory work in embryology courses should be given in the textbook. The treatment of lymphatics is especially deficient. The illustrations could be improved, some are completely unacceptable.

A typical shortcoming of the book is shown in the following example of the insufficiency of a too brief—or unskilful—presentation. The student who wants to know is not helped by statements such as this on page 12 at the end of the chapter on histological development: "The last fifty years have seen the gradual development of an interaction theory, based on (1) definite localization of genes on the chromosomes (Morgan 1910), (2) the modification of the action of genes by specific extrinsic factors such as chemicals (Stockard, 1909), temperature (Krafka, 1920), x-ray (Job, 1935), endocrines (Young 1937), 'organizers' (Spemann, 1938), effective at 'critical moments' in development." If the purpose of providing smaller textbooks is to conserve the student's time, he is not being

helped by a discussion which consists essentially of references to the original literature. The function of the author is to abstract the literature for the student, to present the most important questions, controversies and conclusions and to give or withhold references to the original literature according to his pedagogic inclinations.

The strongest feature of the book as contrasted with its many deficiencies is its insistence on human material, with reliance on that of the primates where the former is lacking. The recently obtained early human "ova" of Hertig and Rock make unnecessary much of the comparative data usually given. (Incidentally, why is a fertilized egg an ovum?) One may sympathize with the aims but be disappointed over achievements of this book.

A Text Book of Fractures and Dislocations Covering Their Pathology, Diagnosis and Treatment. By Kellogg Speed S.B. M.D. F.A.C.S. Professor of Surgery (Rush) of the University of Illinois Chicago. Fourth edition. Cloth. Price \$12.50. Pp. 1106 with 1140 illustrations. Philadelphia: Lea & Febiger 1942.

In this edition Speed presents the subject from the point of view of the principles involved and discusses treatment, as he states in his preface, on the basis of experience. To those seeking a quick reference work for a standard method of treating a fracture, the book may be somewhat disappointing. To students and practitioners, however, who want an understanding of the principles underlying the care of fractures it is highly satisfactory. The anatomic and physiologic facts relating to injuries in each region are briefly and clearly presented. Reproductions of roentgenograms, line drawings and photographs are used throughout the text and, with their terse descriptive titles, add much to the book. Each chapter is followed by a bibliography. The index of subjects which follows the text is complete. The first chapter which deals with emergency handling of fractures, general methods of reduction, roentgenology, anesthesia and the technic of splinting, contains many valuable practical points. The second chapter, on the general outline of treatment of fractures, discusses minor and major procedures used, as well as indications for and against open operations. In the discussion of individual fractures throughout the rest of the book, these points of treatment are elaborated. It is evident throughout that the author is not in favor of the present tendency to standardize the technic for each fracture but insists on adapting the treatment to the particular circumstances. Consequently he discusses principles at length and outlines several technics which have been tried and found useful. His emphasis on the common complications and difficulties in handling various fractures adds greatly to the value of the book. The volume is long for any one looking for quick and easy information on the treatment of fractures. For those however who want an adequate discussion of the principles of fracture treatment this book is one of the best references for students and practitioners.

Divertículos idiopáticos del duodeno. Por Manuel S. Gultarte. Tesis de doctorado. Universidad nacional de Buenos Aires. Facultad de ciencias médicas. Escuela de medicina. Paper. Pp. 110 with 65 illustrations. Buenos Aires: Sebastián de Amorrotu e Hijos. El Ateneo. 1941.

The concept of intestinal diverticula purely as a postmortem finding belongs to the past. Although no sign can be considered as pathognomonic a careful analysis of the symptoms may anticipate in many cases what the radiologic examination will show more conclusively. This is the idea that the author develops in his thesis on the basis of the experience gained from a careful study of several patients. The prognosis and treatment of the condition are also considered, and the literature (two hundred and eighty-one references) is carefully reviewed.

Contribución al estudio de la epilepsia experimental en el hombre. Por el Dr. Isaac Roimiser. Tesis de doctorado. Universidad nacional de Buenos Aires. Facultad de ciencias médicas. Paper. Pp. 132 with illustrations. Buenos Aires 1942.

Epileptic attacks of 38 patients as induced by pentamethylene were studied. This and analogous drugs have made possible an objective and controllable study of epilepsy comparable in every way to the spontaneous disease. Although the chief purpose of the author was the experimental study of the condition—and he does it quite thoroughly—the beneficial therapeutic effects observed are also recorded. The thesis is really a good monograph on the disease which the specialist would enjoy reading.

TRANSMISSION OF FILARIA

To the Editor—An article by Dr. Earl S. Taylor (*The Journal*, Dec. 20, 1941, p. 2123) states that syphilis, malaria, influenza, measles, allergy, smallpox, and diseases caused by the rickettsia organisms and in the Orient, parasitic diseases such as filaria have been reported as transmitted by transfusion of whole blood. As far as I know, microfilariae must be sucked up by a mosquito in whose body they undergo a definite biologic cycle. When the cycle is completed they get into the proboscis and when the mosquito bites they break through the labium and actively penetrate the skin, presumably at the point of puncture by the mosquito. Filaria worms for example *Wuchereria bancrofti* do not live in the blood but in lymph spaces. Microfilariae are liberated into the blood but when they are in the blood they are not infective as they are just embryos which can further develop only in the mosquito. Would you be kind enough to tell me whether or not Dr. Taylor was right in his assumption that filarial diseases may be transmitted by the transfusion of whole blood and if so whether any such cases have been reported?

Rudolf W. Kogan, Minneapolis

ANSWER—Filaria infections cannot be transmitted directly by the transfusion of whole blood. The embryos (microfilariae) which circulate in peripheral blood need to be picked up by a susceptible blood sucking fly in its blood meal after which they migrate from the fly's stomach to its thoracic muscles, where they metamorphose through a series of larval stages and migrate down the fly's proboscis sheath to enter the skin the next time the fly bites a human being. It is true, however, that microfilariae may be transferred from an infected individual to a filaria free person and may survive up to six weeks or more.

SENSITIVITY TO COCAINE AND IODINE BEFORE BRONCHOGRAPHY

To the Editor—A recent issue of the *Lancet* or the *British Medical Journal* contained a statement that before one performs transcathectomy bronchography patients should be tested for sensitization to iodine and cocaine. Can you give me a description of standard or generally employed tests for this purpose?

M. D. Iowa

ANSWER—Search of the literature reveals little information regarding tests for sensitivity to cocaine and iodine. As regards cocaine or cocaine substitutes, caution is strongly advised. Emil Mayer (*THE JOURNAL*, March 15, 1924, p. 876), heading a committee which investigated the toxic effects of local anesthetics, reported forty-six deaths, of which twenty-six were due to cocaine alone or with procaine. Some of these patients also received epinephrine to reduce local bleeding but Mayer believes that the addition of epinephrine in amounts of 1 mg. or more to a solution of cocaine often increases the toxicity of the cocaine. He suggests that it is unsafe to inject more than 10 minims of a 1:10,000 dilution of epinephrine when used with cocaine or more than 1 mg. with procaine. Mayer also advises that in operative procedures in the larynx or bronchi cocaine be used in 10 per cent dilution, with two applications, totaling not over 15 minims, containing from 1 to 1½ grains (0.06 to 0.1 Gm.). Procaine should not be stronger than 1 per cent.

Louis Pelnar, in a recent report on allergy to iodine (*J. Lab. & Clin. Med.* 27:1150 [June] 1942), found that all 5 of his patients gave positive patch tests to iodine. He merely applied a drop of tincture of iodine to the skin. Within twenty-four hours all the sensitive individuals developed definite redness and swelling at the point of application. Nonsensitive persons were also tested but gave negative reactions. Pelnar says "If this can be shown to be a general finding in other cases it can be used as a diagnostic test." The test is simple and should be tried before iodides are used or tincture of iodine is applied. In Pelnar's series redness and swelling of the eyes and face and a fine scarlatiniform rash occurred in each case. In one case symptoms occurred after a saline laxative was taken which contained a small amount of iodine, in another the cause was a throat lozenge containing calcium iodide. A third patient developed symptoms from an iodoform pack, and the other two were affected by painting with tincture of iodine (1 of these developed thrombopenic purpura).

BUBBLE BATH PREPARATIONS

To the Editor—A white girl aged 3½ years gives a history of rash. For the past year she has been using Bubble Foam and Featherfoam in her bath and I am interested in finding out what ingredients these articles contain. A paste patch did not show local reaction but a symptomatic reaction was noticed on the following day.

John P. Helmick, M.D., Fairmont, W. Va.

ANSWER—The ingredients of bubble bath preparations are salts which produce carbon dioxide when they are dissolved in water. Irritation following such a bath is ordinarily due to the carbon dioxide, a fine erythema sharply limited above at the high water mark. This lasts but a short time and is accompanied by a tingling sensation. Directions given for management of the carbon dioxide bath for therapy specify that the patient should be dried by patting, not rubbing. No report has been found of a persistent dermatitis caused by the carbon dioxide bath.

Another possibility is sensitization to the essential oils used to perfume the bath powder. Patch tests should be made to correspond as closely as possible with the conditions of the bath, the solution of salts diluted as in the bath and the carbon dioxide allowed to pass off before the patch is applied. A negative patch test, however, would not prove that the material tested was wholly innocuous.

OPERATIONS ON INFERIOR OBLIQUE MUSCLE

To the Editor—At the present time three operations are mentioned for correction for an overacting inferior oblique muscle. It seems that tenotomy is no longer in vogue. However, myomectomy of the muscles or recession of the muscles has to be championed. Will you kindly advise me as to whether the more difficult recession has any actual advantage over myomectomy?

M. D., Michigan

ANSWER—No operator is justified in limiting his surgical armamentarium to any one operation on a given tissue. An overaction of an oblique muscle requires a different surgical attack than does an underaction. In the same way an advancement of an oblique muscle must be varied according to the amount and character of the correction desired. Consequently, myectomy, recession and advancement all have their place, and the competent ophthalmic surgeon must be familiar not only with the technique but even more with the indications of each. A short but reasonably adequate discussion of this subject is to be found in the second edition of 'Principles and Practice of Ophthalmic Surgery' by E. B. Speth (Philadelphia, Lea & Febiger, 1941, p. 191).

'STARCH EATING' AND NUTRITIONAL DEFICIENCY

To the Editor—A colored woman has informed me that she eats large quantities of common glass starch such as is used in washing clothes. She tells me that a great many people of her race in this locality eat as much as 2 cups a day. She appears to be in good general health. Is there any harm in this practice?

M. D. Ohio

ANSWER—"Starch eating" is a common dietary idiosyncrasy in certain localities and may lead to the development of deficiency diseases, particularly of vitamins of the B complex. Since starch supplies carbohydrate calories and is devoid of vitamins, protein and minerals, deficiency diseases may develop when calories derived from starch replace calories derived from foods of high vitamin content. If the person merely adds the starch to a diet of optimal vitamin, protein and mineral content, probably no harm would be done.

HYPNOTISM

To the Editor—In *The Journal*, Jan. 23, 1943, page 299, M. D. Puerto Rico is answered regarding the current status of hypnotism as a therapeutic procedure. On the whole the reply is fairly satisfactory, but I object to referring to such a book as 'The Science of Hypnotism' by Alexander Cannon, New York: E. P. Dutton & Co., 1937. Immediately on reading the reply I opened my copy of Cannon's book by chance, at page 87. It reads: "In disease the discomfort is produced by a deficiency in certain vibrations including visual and auditory vibrations, and this means that the tuning fork of the body, the etheric double (which holds the astral to the physical body and should not be mistaken for the etheric body which is still finer than the astral body) is out of tune and needs adjustment. The correct colour is found which is required for the replenishing of the deficiency of the spectrum and the correct sound should also be dealt with by the use of gramophone records, choosing the right type of music which corrects the deflected auditory vibrations. The etheric vibrations of the higher realms are still unaffected and can be adjusted by hypnosis or such state induced by colour vibrations alone, auditory vibrations alone, or better still the two combined. Perfumes all of which are small vibrations also affect the human vibrations for good or evil. This can be observed in daily life. The constant smell of animals has often caused certain forms of insanity. I have used the Irwin colour filters for producing sedative, recuperative and stimulative influences upon the mind of man. The Deighton Patmore psychic light (which consists of a red lamp surrounded by an orange bowl) brings out latent mediumship and hypnophilia. Unfortunately such is the type of reference in one instance suggested to some one seeking reliable information. I hope you will correct this."

HYPERTENSION IN PEOPLE OVER FORTY

COMMANDER A M MASTER, MC-V(S), USNR
H H MARKS AB

BETHESDA, MD

AND

CAPTAIN SIMON DACK

MEDICAL CORPS, ARMY OF THE UNITED STATES

In a previous communication we¹ intimated that the incidence of hypertension in the general population over 40 and 50 was higher than was generally appreciated. This has been confirmed in preliminary reports on the incidence of hypertension in workers over 40 and in general hospital patients. In this report we now summarize the blood pressure readings in nearly 15,000 men and women over the age of 40.

The problem of hypertension is a fundamental one. Together with coronary sclerosis it is the most common form of heart disease and probably is the largest single cause of death. This is doubly so if only those over 40 are considered. Furthermore, hypertension is important in respect to the role it plays in other diseases, e g arteriosclerosis of the cerebral, renal and coronary vessels.

The incidence of hypertension in persons over 40 has become increasingly important because there are now millions of people who survive this age.² One third of the present population is 40 years or over³ and it has been estimated that in 1980 nearly one half will be.⁴

The literature on hypertension is voluminous. Yet reports on the incidence of hypertension in large series of people over 40 years of age have been few. In the few reports that discuss hypertension in older age groups the number of cases has been too small to be

reliable, often only 100 cases.⁵ Furthermore, frequently only blood pressure averages for each age group are given, but these are not helpful in determining the incidence of hypertension.

The tremendous material presented by insurance statistics cannot be used, since they consist of a selected group. People with serious degrees of hypertension either do not present themselves to the insurance companies or are rejected and therefore not included in the published figures. Nevertheless, that the blood pressure increases with age is definite.

MATERIAL

We have collected blood pressure readings on 14,849 persons over 40 years of age (tables 1 and 2). There were 5,737 workers,⁸ none in industries exposed to poisons, 2,610 residents of homes for aged,⁹ rather than homes for aged and sick, and finally 6,502 patients in a general hospital (Mount Sinai New York City) in which only a small percentage were admitted for hypertension or its complications. There were 8,483 men and 6,366 women. The material was divided according to sex and ten year age groups. All the groups, except that comprising the ages 90 to 99, were of sufficient size to give statistically reliable results (tables 1 and 2).

METHOD OF TAKING BLOOD PRESSURE

All the blood pressures were taken by the auscultatory method by physicians. In the industrial concerns the blood pressure readings of the women were nearly always taken by women doctors.

In nearly two thirds of the readings the diastolic pressure was taken at the fifth phase—the complete disappearance of sound rather than at the fourth phase—the definite diminution in intensity. The American

that had the former method been consistently employed the percentages of hypertension in our series would be higher.

In our preliminary reports, we² have already presented in detail our reasons for concluding that our cases are representative of persons in middle and later life in the general population as a whole and therefore summarize them here only briefly. Among the industrial cases over 40, every type of worker was represented: clerk, telephone operator, longshoreman, linesman, chauffeur, laborer, executive and others. The data were obtained from companies possessing a complete medical service, where the individual is examined at application for employment and often regularly thereafter at six or twelve month periods, where voluntary examinations may be had at any time, where complete records are kept and where necessary precautions are taken to obtain correct blood pressures. Thus, these blood pressure readings are dependable. Although we were assured by the medical directors that only a very high blood pressure would bar an applicant from employment, it may be that in times when jobs are scarce hypertension may be used as an excuse not to hire an applicant. On the other

hand, workers were not discharged for uncomplicated hypertension. To a slight extent our figures are low, since they would not include hypertensives rejected on application for a job. As already indicated, records of employees were excluded if the workers were exposed to toxic chemicals, fumes and so on, which affect bodily health and blood pressure.

With regard to the hospital material obtained from the Mount Sinai Hospital, New York,^{2a} the data were derived from all types of patients in a large institution of 1,000 beds, consisting of open wards and semiprivate and private patient pavilions. There is no unusual concentration on any specialty, and cases included are drawn from every department—medicine, surgery, neurology, gynecology, otolaryngology, ophthalmology and others. All classes of people, rich and poor, banker and laborer, are represented.

To be sure that the admissions to the hospital for hypertension, hypertensive heart disease or heart failure and cerebral apoplexy were not significantly high, three hundred charts of each decade except the ninth were sampled. If a patient was admitted for hypertension and another disease, e.g. diabetes, and there was any doubt as to the primary condition, we classified it as a hypertension admission. It is evident from table 3 that admissions for hypertensive disease or its direct com-

or contributed his entire savings for his future upkeep. Probably two thirds of the residents did this. Protestants, Catholics and Jews were represented, less than one fourth were Jews. Complete records of blood pres-

being too liberal, chiefly on the basis of insurance mortality studies.¹³ Some authorities now set the limit of beginning hypertension as low as at 140 mm systolic or 90 mm diastolic. In recognition of the arbitrary nature of the classification of hypertension we are reporting the facts on the basis of seven definitions, namely 140/90 or over, 150/90 or over, 150/95 or over, 150/100 or over (with either the systolic or diastolic pressure qualifying the case for the particular class), 150 mm systolic or over, 90 diastolic or over and 95 diastolic or over (tables 1 and 2).

RESULTS

Tables 1 and 2 give the combined results for the three broad classes of persons included in the study, subdivided according to age and sex, and these facts are presented graphically for men and for women in charts 1 and 2 respectively. Because of the relatively small number of cases over the age of 90, the changes between the ninth and tenth decades of age are indicated by broken lines.

On the basis of the customary limit of hypertension, 150 and/or 90 or over, a little over one fourth of the men have hypertension at ages 40-49, a little over two fifths in the next decade, considerably more than half in those 60-69, nearly two thirds in 70-79 and slightly more in the ninth decade. Among women the general contour of the age curve bears a general resemblance to that for males, but the proportions are much higher,

Chart 1—Hypertension in men aged 40-99

sure were kept in all instances and competent physicians made a physical examination once or twice a year regularly.

It is true that no one group, either workers, hospital patients or residents in the homes for the aged, is representative of the population as a whole. The incidence of hypertension was not identical for these three groups. However, since the aggregate is based on all classes of the population, it may be considered to be a fair cross section of it.

LIMITS OR DEFINITION OF HYPERTENSION

Clinicians and insurance investigators¹² have for years been interested in the limits to be used for hypertension. The definition of the latter is by no means specific. Various authors have used different lower limits of systolic and diastolic pressures, and in much of the earlier literature, and even some current literature, hypertension is defined merely in terms of the systolic. Some authors have related the lower limit to an arbitrary figure above the average for the age. In the past, a lower limit of 150/100 was in common use, but this was subjected some years ago to criticism as

Chart 2—Hypertension in women aged 40-99

there being characteristic differences in the level and the steepness of the curves. In the first age group, 40-49 almost a third have hypertension, more than half

in the next decade, more than two thirds in the seventh decade and about three fourths in the eighth and ninth decades

Turning to the lowest limit of hypertension namely 140 and/or 90 or over, it is found that about one third of the men between 40 and 49 years of age have hypertension, but this proportion increases rapidly for the next three decades, until it is over three fourths in the eighth. Among women the incidence of hypertension of this degree is approximately 40 per cent between the ages 40 and 49 rising rapidly and exceeding the three quarter mark between 60 and 69. The proportions continue to increase but more slowly, through the ninth decade when 85 per cent of the women have a blood pressure of 140/90 or over.

A study of the charts reveals that for all the seven limits of hypertension used, the incidence of hypertension rises with each decade until the age of 80. The curves containing systolic blood pressure limits rise, in fact until 90. The percentage is always higher in women.

When only diastolic blood pressure is considered there is found to be a definite lag in the upward slope of the curve of blood pressure with age beginning at the age of 60, and in men the proportion actually falls after age 80. This emphasizes the well known observation that the systolic rises more than the diastolic with age thus causing the pulse pressure to increase.

It is of interest to see how great the proportion of hypertensives is among persons in the general population who are past their fortieth birthday on the assumption that our findings are representative. Computations of this type, taking into account the increase in the proportion of cases with high blood pressure with advancing age have been made on the basis of the age distribution of the white population of the country at the census¹⁴ of 1940. These computations have been done for several broad age groups viz 40 and over 50 and over 60 and over and 70 and over according to three of the definitions of hypertension (table 4).

By the most liberal definition of hypertension 140/90 or over, practically half the male population and 60 per cent of the female population 40 years of age and over are hypertensive. These proportions increase rapidly so that among persons 70 and over more than three fourths of the men and four fifths of the women have high blood pressure of this degree. Even by the much

population has a smaller proportion of persons at the ages past 60 than is true for the rest of the country.

The proportion of Negroes in our series is much lower than in the total population. If allowance should be made for this factor it would increase our figures somewhat, since hypertension has been reported to be appreciably more frequent in Negroes¹ than in white persons.

TABLE 4—Estimated Incidence of Hypertension of Various Degrees Among White Persons in the General Population Over Age 40

Based on the incidence in the survey and the age distribution of the population of the United States in 1940

	60 and over	47	60.5
	70 and over	61.8	70.4

Cases not included if either the systolic or the diastolic is within the specified limit

Since most of the persons included in the study were residents of New York City which has a large Jewish population, it might be inferred that this was a major factor in the high incidence of hypertension reported. However only among hospital cases were Jews in the majority—about 60 to 65 per cent. As regards homes for the aged three fourths of the patients were non-Jewish. The proportions in the industrial cases are not known exactly but probably less than 10 per cent were Jewish. It is significant also that practically the same ratios of hypertension were observed in the different industrial concerns we have used in our study whether located in New York or elsewhere.¹⁵

COMMENT

It is surprising that there has not been an appreciation of the prevalence of hypertension in people over 40 or 50 years of age. However the indications of this high prevalence have been present if one searched for it since numerous papers¹⁶ have shown that the average blood pressure goes up with age. Although the recording of average blood pressure in an age group is no help in respect to the incidence of hypertension, the paper of Britten and Thompson¹⁷ and also the recent one of Miller¹⁸ show a distinct trend of increase in hypertension with age. Thus, analysis of the data of Britten and Thompson shows in 2,638 male workers an incidence of hypertension (150 mm) of 16.0 per cent in ages 40-49, 28.6 per cent in ages 50-59 and actually 51.2 per cent in the age of 60 years or over. These authors inferred that the high incidence of hypertension at the

TABLE 3—Hospital Admissions for Hypertension or Its Complications

Age Group	Male	Female
40-49	2.0%	2.5%
50-59	5.2%	7.2%
60-69	3.2%	13.6%
70-79	4.8%	8.5%

more conservative definition of 150/100 or over about one third of the male population and over two fifths of the female population at ages 40 and over have high blood pressure. This percentage also rises rapidly, so that it is present in more than a majority of men 60 and over and of women 50 and over.

In New York City, where most of the fundamental material was derived, the proportions would be slightly lower. The reason for this is that the New York City

older ages was common only to workers. As already stated, Saunders and Bancroft¹⁹ found a 62.3 per cent incidence of hypertension (systolic 150 mm or more) in female Negroes of ages 50-59, 73.5 per cent of ages 60-69 and 73.1 per cent over 70. These investigators explained their findings away on the basis of poverty of the people and the frequency of avitaminosis among them.

Our survey of persons over 40 shows such high proportions with hypertension of slight and moderate degree that we believe it calls for some revision of our point of view as to what is normal for persons in middle and later life. It may well be that the definition of hypertension needs to be liberalized. For clinical medicine, certainly, if at least half the persons over 50 have a blood pressure of at least 150/90 it can hardly be said that such a degree of hypertension is abnormal. This point of view does not in any way conflict with the fact that pressures below this level are more favorable for longevity. We do not say, for example, that a man 60 years old with blood pressure 160/95 will live as long as one whose blood pressure is 120/80. That cannot be predicted for the individual. The chances are better for the man with the lower blood pressure because, when groups are considered, the mortality of those with higher blood pressure is appreciably in excess of those with low blood pressure. As far as longevity is concerned, insurance studies clearly show that the hypotensive have the best outlook. Richter²⁰ noted the frequency of very low blood pressures in very old persons. To the extent that the expected longevity is a rough index of physical and mental well-being, Robinson²¹ may be correct in saying that hypotension is ideal, but we believe that he is wrong in intimating that the blood pressures beyond 140 or 150, let alone any blood pressure over 120, are 'pathologic'. It may well be that these higher pressures are a general and early indication of cardiovascular degeneration. But, of themselves, such pressures cannot be looked on as pathologic. Group longevity is not the sole criterion. Experience shows that in many persons hypertension is not incompatible with a high degree of mental and physical efficiency over long periods of time.

The data of this survey permit the construction of frequency distributions of blood pressures for persons over 40 and the computation of the normal range according to various statistical criteria. The preparation of this material is under way.

That the high percentage of hypertension in the population over 40 and particularly over 50, is no cause for alarm should be evident. Rather, it should be a means of reassurance since a slight, perhaps even a moderate, degree of hypertension can no longer be considered abnormal at these ages. Fahr²² and Wiggers²³ feel that it is compensatory to the loss of elasticity that occurs in aging blood vessel walls. Since the aorta has lost its elasticity at each systole, the blood pressure is high. This physiologic reasoning also explains the

increase in pulse pressure with age,²⁴ for during diastole, as the blood flows off to the tissues of the body, the pressure falls rapidly since there is little elastic recall to the vessel wall. One might even hazard the opinion that the arteriosclerosis causes the hypertension and not vice versa.

We have mentioned the tendency of our curves to flatten after the age of 70, but the systolic hypertension certainly and even the diastolic (except in men from 80 to 89) rises until the age of 90. This is contrary to most series reported, which show a fall after the age of 65. Wildt²⁵ however, found in his small series a rise to 90. Saller's²⁷ data indicate a rise in blood pressure past 70 years of age. Wetherby²⁸ found increasing average blood pressure in older persons, but his data, based on the age group 70 and over, give no clue as to the situation in extreme old age. Undoubtedly the discrepancy is due to the fact that the number of cases in the age groups between 65 and 90 cited by previous investigators was very small, often consisting of 100 or 150 cases, including both men and women.

Concerning the absolute level of incidence of hypertension after the age of 90 we can say nothing, since the number of cases here is too small. We have used broken lines in the graphs to indicate this uncertainty.

SUMMARY

Since hypertension is most common in persons over 40 and because of the greatly increased number of people surviving this age, the incidence of hypertension at these ages is important.

The 15,000 persons in the survey (8,483 males and 6,366 females) represent a good cross section of the population in middle and later life. In each decade of life from the fifth to the ninth the size of the samples was sufficient to give statistically reliable results. The blood pressure readings were dependable.

The incidence of hypertension in each decade of life was determined according to seven limits namely 140/90 or over, 150/90 or over, 150/95 or over, 150/100 or over, 150 mm or over systolic, 90 or over diastolic and 95 or over diastolic.

In each decade of age a large proportion of persons were found to be hypertensive. This was true particularly of systolic hypertension. Among men a majority were hypertensive beginning with age 60 for most of the limits, and among women this occurred in some instances as early as age 50.

The percentages of hypertensive persons by decade were applied to the white population of the United States as constituted in 1940, and it was found that on this basis 41 per cent of the male population and 51 per cent of the female population 40 years of age and over would be expected to have blood pressures of 150/90 or over. At age 50 and over this ratio would be 50 per cent in males and 62 per cent in females; at age 60 and over, 60 per cent for males and 70 per cent for females; and at age 70 and over, 66 and 74 per cent respectively.

in the next decade, more than two thirds in the seventh decade and about three fourths in the eighth and ninth decades.

Turning to the lowest limit of hypertension, namely 140 and/or 90 or over, it is found that about one third of the men between 40 and 49 years of age have hypertension, but this proportion increases rapidly for the next three decades, until it is over three fourths in the eighth. Among women the incidence of hypertension of this degree is approximately 40 per cent between the ages 40 and 49, rising rapidly and exceeding the three quarter mark between 60 and 69. The proportions continue to increase, but more slowly, through the ninth decade, when 85 per cent of the women have a blood pressure of 140/90 or over.

A study of the charts reveals that for all the seven limits of hypertension used, the incidence of hypertension rises with each decade until the age of 80. The curves containing systolic blood pressure limits rise in fact until 90. The percentage is always higher in women.

When only diastolic blood pressure is considered there is found to be a definite lag in the upward slope of the curve of blood pressure with age, beginning at the age of 60 and in men the proportion actually falls after age 80. This emphasizes the well known observation that the systolic rises more than the diastolic with age, thus causing the pulse pressure to increase.

It is of interest to see how great the proportion of hypertensives is among persons in the general population who are past their fortieth birthday on the assumption that our findings are representative. Computations of this type, taking into account the increase in the proportion of cases with high blood pressure with advancing age, have been made on the basis of the age distribution of the white population of the country at the census¹¹ of 1940. These computations have been done for several broad age groups, viz. 40 and over, 50 and over, 60 and over, and 70 and over, according to three of the definitions of hypertension (table 4).

By the most liberal definition of hypertension, 140/90 or over, practically half the male population and 60 per cent of the female population 40 years of age and over are hypertensive. These proportions increase rapidly so that among persons 70 and over, more than three fourths of the men and four fifths of the women have high blood pressure of this degree. Even by the much

population has a smaller proportion of persons at the ages past 60 than is true for the rest of the country.

The proportion of Negroes in our series is much lower than in the total population. If allowance should be made for this factor it would increase our figures somewhat, since hypertension has been reported to be appreciably more frequent in Negroes¹² than in white persons.

TABLE 4—Estimated Incidence of Hypertension of Various Degrees Among White Persons in the General Population Over Age 40

Based on the incidence in the survey and the age distribution of the population of the United States in 1940

Degree of Hypertension	Age Group Years	Percentage	
		Male	Female
140/90 or over	40 and over	43.6	57.8
	50 and over	53.9	71.5
	60 and over	70.5	79.6
	70 and over	77	82
140/80 or over	40 and over	40.9	55.7
	50 and over	50.6	66.9
	60 and over	69.8	78.0
	70 and over	68.8	74.0
140/100 or over	40 and over	26.5	47.6
	50 and over	41	59.5
	60 and over	47	66
	70 and over	61.8	70.4

Cases are included if either the systolic or the diastolic is within the specified limit.

Since most of the persons included in the study were residents of New York City, which has a large Jewish population, it might be inferred that this was a major factor in the high incidence of hypertension reported. However, only among hospital cases were Jews in the majority—about 60 to 65 per cent. As regards homes for the aged, three fourths of the patients were non-Jewish. The proportions in the industrial cases are not known exactly, but probably less than 10 per cent were Jewish. It is significant also that practically the same ratios of hypertension were observed in the different industrial concerns we have used in our study, whether located in New York or elsewhere.¹³

COMMENT

It is surprising that there has not been an appreciation of the prevalence of hypertension in people over 40 or 50 years of age. However, the indications of this high prevalence have been present if one searched for it, since numerous papers¹⁴ have shown that the average blood pressure goes up with age. Although the recording of average blood pressure in an age group is no help in respect to the incidence of hypertension, the paper of Britten and Thompson¹⁵ and also the recent one of Miller¹⁶ show a distinct trend of increase in hypertension with age. This analysis of the data of Britten and Thompson shows in 2,638 male workers in incidence of hypertension (150 mm.) of 16.0 per cent in ages 40-49, 28.6 per cent in ages 50-59 and actually 51.2 per cent in the age of 60 years or over. These authors inferred that the high incidence of hypertension at the

TABLE 3—Hospital Admissions for Hypertension or Its Complications

Age Group	Male	Female
40-49	1.0%	6.6%
50-59	6.2%	7.7%
60-69	2.1%	1.7%
70-79	4.8%	5.5%

more conservative definition of 150/100 or over, about one third of the male population and over two fifths of the female population at ages 40 and over have high blood pressure. This percentage also rises rapidly so that it is present in more than a majority of men 60 and over and of women 50 and over.

In New York City, where most of the fundamental material was derived, the proportions would be slightly lower. The reason for this is that the New York City

older ages was common only to workers. As already stated, Saunders and Bancroft¹⁹ found a 62.3 per cent incidence of hypertension (systolic 150 mm or more) in female Negroes of ages 50-59, 73.5 per cent of ages 60-69 and 73.1 per cent over 70. These investigators explained their findings away on the basis of poverty of the people and the frequency of avitaminosis among them.

Our survey of persons over 40 shows such high proportions with hypertension of slight and moderate degree that we believe it calls for some revision of our point of view as to what is normal for persons in middle and later life. It may well be that the definition of hypertension needs to be liberalized. For clinical medicine, certainly, if at least half the persons over 50 have a blood pressure of at least 150/90 it can hardly be said that such a degree of hypertension is abnormal. This point of view does not in any way conflict with the fact that pressures below this level are more favorable for longevity. We do not say, for example, that a man 60 years old with blood pressure 160/95 will live as long as one whose blood pressure is 120/80. That cannot be predicted for the individual. The chances are better for the man with the lower blood pressure because when groups are considered the mortality of those with higher blood pressure is appreciably in excess of those with low blood pressure. As far as longevity is concerned, insurance studies clearly show that the hypotensive have the best outlook. Richter²⁰ noted the frequency of very low blood pressures in very old persons. To the extent that the expected longevity is a rough index of physical and mental well-being, Robinson²¹ may be correct in saying that hypotension is ideal but we believe that he is wrong in intimating that the blood pressures beyond 140 or 150 let alone any blood pressure over 120, are "pathologic." It may well be that these higher pressures are a general and early indication of cardiovascular degeneration. But, of themselves, such pressures cannot be looked on as pathologic. Group longevity is not the sole criterion. Experience shows that in many persons hypertension is not incompatible with a high degree of mental and physical efficiency over long periods of time.

The data of this survey permit the construction of frequency distributions of blood pressures for persons over 40 and the computation of the normal range according to various statistical criteria. The preparation of this material is under way.

That the high percentage of hypertension in the population over 40, and particularly over 50, is no cause for alarm should be evident. Rather, it should be a means of reassurance since a slight, perhaps even a moderate, degree of hypertension can no longer be considered abnormal at these ages. Fahr²² and Wiggers²³ feel that it is compensatory to the loss of elasticity that occurs in aging blood vessel walls. Since the aorta has lost its elasticity at each systole, the blood pressure is high. This physiologic reasoning also explains the

increase in pulse pressure with age,²⁴ for during diastole, as the blood flows off to the tissues of the body, the pressure falls rapidly since there is little elastic recall to the vessel wall. One might even hazard the opinion that the arteriosclerosis causes the hypertension and not vice versa.

We have mentioned the tendency of our curves to flatten after the age of 70, but the systolic hypertension certainly and even the diastolic (except in men from 80 to 89) rises until the age of 90. This is contrary to most series reported, which show a fall after the age of 65.²⁵ Wildt,²⁶ however, found in his small series a rise to 90. Saller's²⁷ data indicate a rise in blood pressure past 70 years of age. Wetherby²⁸ found increasing average blood pressure in older persons, but his data, based on the age group 70 and over, give no clue as to the situation in extreme old age. Undoubtedly the discrepancy is due to the fact that the number of cases in the age groups between 65 and 90 cited by previous investigators was very small, often consisting of 100 or 150 cases, including both men and women.

Concerning the absolute level of incidence of hypertension after the age of 90 we can say nothing since the number of cases here is too small. We have used broken lines in the graphs to indicate this uncertainty.

SUMMARY

Since hypertension is most common in persons over 40 and because of the greatly increased number of people surviving this age, the incidence of hypertension at these ages is important.

The 15,000 persons in the survey (8,483 males and 6,366 females) represent a good cross section of the population in middle and later life. In each decade of life from the fifth to the ninth the size of the samples was sufficient to give statistically reliable results. The blood pressure readings were dependable.

The incidence of hypertension in each decade of life was determined according to seven limits, namely 140/90 or over, 150/90 or over, 150/95 or over, 150/100 or over, 150 mm or over systolic, 90 or over diastolic and 95 or over diastolic.

In each decade of age a large proportion of persons were found to be hypertensive. This was true particularly of systolic hypertension. Among men a majority were hypertensive beginning with age 60 for most of the limits, and among women this occurred in some instances as early as age 50.

The percentages of hypertensive persons by decade were applied to the white population of the United States as constituted in 1940 and it was found that on this basis 41 per cent of the male population and 51 per cent of the female population 40 years of age and over would be expected to have blood pressures of 150/90 or over. At age 50 and over this ratio would be 50 per cent in males and 62 per cent in females, at age 60 and over, 60 per cent for males and 70 per cent for females, and at age 70 and over, 66 and 74 per cent respectively.

28 Wetherby, Macnider. A Comparison of Blood Pressure in Men and Women. A Statistical Study of 5,440 Individuals in The Kidney in Health and Disease. edited by Hilding Berglund and Grace Medes. Philadelphia Lea & Febiger 1935 p 370.

It was found that, regardless of the classification, the incidence of hypertension rose with each decade of age up through the eighth decade, and in the case of systolic hypertension up through the ninth decade. The incidence of hypertension was higher in women and rose precipitously between 40 and 60 years of age, faster than in men.

Systolic hypertension increased more rapidly than diastolic hypertension, resulting in an increase of pulse pressure with age.

The presence of hypertension at age 40 and over is so common that a mild degree and perhaps even a "moderate" degree can no longer be considered abnormal. Limits of normal blood pressure at these ages should therefore be raised. The material of the survey is being analyzed to develop such standards.

THE RELATION OF VASCULAR DISEASE TO THE HYPERTENSIVE STATE

BASED ON A STUDY OF RENAL BIOPSIES FROM ONE HUNDRED HYPERTENSIVE PATIENTS

BENJAMIN CASTLEMAN, M.D.

AND

REGINAID H. SMITHWICK, M.D.

BOSTON

The gross and microscopic appearance of the kidneys of hypertensive patients dying of renal failure or any other complication such as coronary disease, heart failure or cerebral hemorrhage has been fairly well established from postmortem studies. The almost constant finding of renal arteriolar disease in these cases has led many people to believe that increased peripheral resistance to blood flow offered by generalized arteriolar disease, especially of the kidneys, is the cause of hypertension. Moritz and Oldt's¹ comparative study of the arterioles of 100 hypertensive and 100 nonhypertensive persons showing that 97 per cent of the hypertensive and 12 per cent of the nonhypertensive persons had renal vascular disease seemed confirmatory evidence of this premise. The other school of thought is that the arteriolar disease is secondary to the hypertension, the cause of which is still unknown. The presence of severe arteriolar damage at the end stage of the disease, as seen in autopsy material, does not necessarily indicate primary arteriolar disease. Outside of experimental hypertension in animals, opportunities for study of the kidneys in the various stages of hypertension have been too few to warrant any definite conclusions.

The surgical treatment of hypertension by dorso-lumbar sympathectomy has afforded us the unique opportunity to examine the kidney grossly through this operative field and to take a biopsy. It was hoped that, if enough renal biopsies taken from hypertensive patients in all stages of the disease could be studied, light could be shed on the relation of the vascular disease to hypertension. During the past two years we have collected renal biopsies from more than a hundred hypertensive patients. This report will be based on a study of the first 100 cases.

CLINICAL DATA

The 100 patients in this series ranged from 18 to 56 years of age, the average being 39. Table 1 shows their distribution by decades. There were 43 males and 57 females. Their symptoms, which included headache, fatigue and occasionally visual disturbances had been present from one month to fifteen years, the average being approximately six years. Most of them had systolic blood pressures over 200 mm. of mercury and diastolic pressures well over 100. The average systolic pressure was 210 and the average diastolic 130. Renal function determined by the phenolsulfonphthalein test showed that 60 per cent had normal function, that 20 per cent had a moderate reduction in excretion of the dye and that 20 per cent had a decided reduction. Renal clearance observations were performed on 20 of these patients, 15 of whom showed normal function by the phenolsulfonphthalein test. Of these 15, all but 3 showed diminished creatinine clearance and renal blood flow.

The cyclogram changes were classified into four grades: grade 1 showed various degrees of arteriolar narrowing or constriction without nicking of venous crossings; grade 2, arteriovenous compression and narrowing, caliber changes, tortuosity or wide light reflexes in the arterioles; grade 3, retinal exudates or hemorrhages in addition to the other types of arteriolar changes; and grade 4, edema of the optic disks with measurable elevation usually with exudate and hemorrhage and any or all of the other changes mentioned. In this series of cases there were 32 per cent of grade 1, 28 of grade 2, 26 of grade 3 and 14 of grade 4. Five cases in which there was edema of the optic disks without measurable elevation were graded 1, 2 or 3 according to other changes. They may very well, however, have been in the earliest phase of malignant hypertension and might have been placed in grade 4. From these clinical data it is apparent that all stages of the hypertensive state are represented in this group of 100 hypertensive patients. Their renal biopsies, therefore, should provide fairly well balanced material to study the relation of the renal vascular disease to hypertension.

TECHNIC

The selection of cases for sympathectomy will not be discussed here. Other significant clinical data concerning this group of cases and others as well will be reported in another communication. The operative procedure has previously been described by one of us.² In brief, it consists of a bilateral extensive splanchnic denervation, the great splanchnic nerves being removed from the semilunar ganglion to approximately the mid-thoracic level and the sympathetic trunk being resected from the ninth dorsal to the first or second lumbar ganglion inclusive. Occasionally the third lumbar ganglion is removed as well. The operation is performed in two stages, one side being done about ten days after the other. The exposure at this operation allows for accurate examination of the adrenals and kidneys which was done in all cases. No abnormalities of the renal artery or vein were noted other than congenital variations such as aberrant vessels to the upper pole or lower pole or both. Most kidneys were found to be

From the Departments of Pathology and Surgery, Massachusetts General Hospital.

² A more detailed account of the correlation of these findings with renal biopsies (Talbot, J. H., Castleman, Benjamin, Smithwick, R. H. and Melville, R. S., Renal Biopsy Studies Correlated with Renal Clearance Observations in Hypertensive Patients Treated with Radical Sympathectomy) is to be published in the *Journal of Clinical Investigation*.

³ Smithwick, R. H. A Technique for Splanchnic Resection for Hypertension. *Surgery* 7: 1-8 (Jan.) 1940.

of normal size. In order to observe the cortical surface, the capsule was incised with a scalpel and by means of a groove director was gently reflected over an area approximately 3 cm in diameter. The large majority of kidneys had fairly smooth surfaces, a few were slightly granular and some had definite small scars. A wedge shaped specimen 6 to 7 mm wide and 5 mm deep was removed with a scalpel only forceps not being used to prevent any injury to the tissue. The specimen was immediately dropped into a bottle of Zenker's fixative. The biopsy wound was sutured with cotton or silk and covered with a small piece of adjacent fat. No complication occurred as a result of the biopsies. In 25 cases biopsies were taken from both kidneys and in every instance the microscopic appearance on the two sides was essentially the same.

MICROSCOPIC APPEARANCE OF THE RENAL BIOPSIES

Pathologists are so accustomed to the microscopic appearance of the hypertensive kidney from autopsy material with the usual postmortem changes that at the beginning of this study some of the findings due to the early fixation (a matter of seconds) seemed so conspicuous that they were at first believed to be pathologic. One of these is the strong accentuation of the basement membrane of the straight tubules, especially of the atrophic ones in the region of a small scar, best brought out by the van Gieson stain. The rapid fixation does not allow for the usual postmortem shrinkage of the epithelial cells in the convoluted tubules, so that these cells appear ballooned out and are filled with coarse granules, and almost all meet in the center, so that only a very small lumen, which is filled with granular material, is left. The glomerular capillaries in contrast seem more widely patent than in postmortem material.

The various types of renal vascular disease have been fully described in the past. One of the best papers on the subject is that by Moritz and Oldt,¹ and we have used their classification: intimal hyalinization, medial hypertrophy and degeneration and endothelial hyperplasia. Their comprehensive description and beautiful colored drawings of these various types of arteriolar sclerosis leave nothing to be added, and the reader is referred to this work for the detailed morphology. We arbitrarily divided the vessels studied into four groups: small arterioles, under 25 microns in external diameter, large arterioles, 25 to 50 microns in diameter, small arteries, 50 to 100 microns in diameter, and large arteries, over 100 microns. Since the biopsies were taken from the peripheral cortex, very few of the large arteries were available.

Most of the biopsies that showed vascular changes contained examples of all types. Except for endothelial hyperplasia, which was found only in the arteries and some of the large arterioles, the intimal and medial changes were observed in vessels of any size. Usually no one type of vascular change was found exclusively in a given biopsy. These findings are similar to those observed by Moritz and Oldt in their autopsy series. No necrotizing arteriolitis or change in the juxta-glomerular apparatus was observed.

We graded each biopsy according to the severity of its vascular disease without knowledge of any clinical data about the patient, and it was found that there were enough differences in the degree of vascular disease to classify the group into 5 grades: grades 0, 1, 2, 3 and 4. The biopsies showed that a very few patients, usually the older ones, had an occasional focal scar with

vascular disease in it. These scars are seen so often in nonhypertensive patients that it was felt that they should not influence the grading of the generalized vascular condition. This policy was also employed by Moritz and Oldt.

GRADE 0 RENAL VASCULAR DISEASE

There were 7 cases in which the biopsy showed no vascular disease. The absence of vascular disease in this group was confirmed by Drs. T. B. Mallory and A. R. Moritz. Two of these patients had biopsies taken from both kidneys and they were essentially the same. There were 4 women and 3 men, they averaged 37.7 years of age and had normal renal function. One interesting feature of this group is that 3 of the patients had adrenal tumors: two cortical adenomas and one pheochromocytoma.⁴ The patient with the latter tumor had no symptoms of paroxysmal hypertension. A fourth patient in this group had symptoms suggestive of a hyperactive medullary tumor, but bilateral exploration and biopsy of the adrenals were negative.

GRADE 1 RENAL VASCULAR DISEASE

There were 21 patients, 11 men and 10 women with an average age of 40, in the group with grade 1 disease. The vascular disease in this group was so slight that at a cursory examination in many instances it might

TABLE 1—Age Distribution

Age	Patients
10-19	1
20-29	15
30-39	34
40-49	40
50-59	10
	100

well have been missed. The number of vessels involved was relatively small and much of the involvement was observed first in sections stained for elastic tissue by the van Gieson and Weigert method. All types of vascular disease were present, but it seemed that intimal hyalinization of the arterioles and arterial endothelial hyperplasia predominated. The amount and degree of vascular disease in this group was so slight that it is very unlikely that renal ischemia produced by vascular narrowing played any mechanical role in the production of the hypertension. One patient in this group had an adrenal cortical adenoma.

GRADE 2 RENAL VASCULAR DISEASE

There were 25 patients, 17 women and 8 men averaging 41.2 years of age, whose renal biopsies were classified as grade 2. Here the vascular disease was more advanced than the minimal changes seen in grade 1 but still not severe enough to be put with the large group 3 in which vascular disease was apparent even at a cursory glance with low magnification. In grade 2 an occasional hyalinized glomerulus was seen but by and large the vascular disease could be considered as mild. One patient in this group had an adrenal cortical adenoma.

GRADE 3 RENAL VASCULAR DISEASE

Grade 3 patients were those whose biopsies showed vascular disease usually severe in degree in every vessel. There were many more scars and hyalinized glomeruli

⁴ A more detailed discussion of the incidence of adrenal tumors in this series of cases will be reported separately.

in a fair proportion of this group, but others showed apparently normal widely patent capillary tufts. Medial arteriolar hypertrophy seemed to predominate in this group. There were 33 patients in this group, 22 women and 11 men, their average age was 36.8 years. Two patients in this group had an adrenal tumor—one, a cortical

TABLE 2—Correlation of Renal Biopsies with Renal Function

Grade 1	21	17	3	1
Grade 2	2	16	6	—
Grade 3	33	19	6	8
Grade 4	14	1	0	8
	100	60	20	20

adenoma and the other both a pheochromocytoma on the right side and a cortical adenoma on the left. The latter patient did not have paroxysmal hypertension.

GRADE 4 RENAL VASCULAR DISEASE

Fourteen patients, 10 men and 4 women with an average age of 42 years, had the most severe renal vascular disease. Every vessel was involved, many glomeruli were scarred and surrounding tubules were atrophic. Except for the absence of necrotizing arteriolitis, these biopsies suggested the so-called malignant nephrosclerosis and all but 1 patient did have decreased renal function. It might be argued that these patients should not have been subjected to sympathectomy because of their imminent uremia. Although this is probably true of some of this group, others have apparently been benefited, a few in a striking fashion.

THE QUESTION OF PYELONEPHRITIS

A few of the biopsies, more from grade 4 than from the other groups of patients, showed changes consistent with chronic or healed pyelonephritis according to the criteria of Weiss and Parker.⁵ Not all of these patients gave a history of old or chronic urinary infection, while a few with a definite pyelonephritic history showed no evidence by biopsy. It was felt, however, that a definite diagnosis of pyelonephritis was not warranted from a small biopsy which did not include any medulla.

CORRELATION OF RENAL FUNCTION WITH RENAL VASCULAR CHANGES

Renal function as measured by the phenolsulfonphthalein test showed normal excretion in 60 per cent of all the cases. When divided into their biopsy grades, it is apparent from both table 2 and chart 1 that renal function is poorer the more severe the vascular disease. These results are obviously what is to be expected, however, and constitute confirmatory evidence of the accuracy of our microscopic gradings. For example, 81 per cent of patients with grade 1 renal vascular disease had normal excretion while 93 per cent of those with grade 4 disease showed impairment in renal function. There were, of course, exceptions such as 1 case of grade 1 in which there was very poor function and 1 case of grade 4 in which there was normal function. It should be emphasized that ordinary renal function tests may fail to detect early evidence of vascular disease and usually are normal or only slightly reduced when grade 3 vascular disease is present.

CORRELATION OF RETINAL VESSELS WITH RENAL VASCULAR CHANGES

The four grades of retinal change were described under clinical data. In many clinics quantitative estimation of the severity of a patient's hypertension is based wholly on the eye-ground changes, and for that reason it is interesting to correlate these changes with those in the kidney. Table 3 shows that there does seem to be some correlation between these two vascular systems in the normal grade 1 and grade 2 renal groups. 5 out of 7 of the normal renal biopsy group showed only grade 1 retinal changes, 81 per cent of the grade 1 renal showed grade 1 or 2 retinal changes. However, even in these groups there were many exceptions. With respect to the grade 3 renal group, all grades of retinal changes were about equally represented. In the grade 4 biopsy group 8 out of the 14 showed severe retinal changes.

THE QUESTION OF MALIGNANT VASCULAR NEPHRITIS AND MALIGNANT HYPERTENSION

In this series of 100 patients there were 14 who clinically fell into the class usually called malignant hypertension. All but 3 of these patients showed either grade 3 or grade 4 renal vascular disease. Nine had impaired renal function as measured by the phenolsulfonphthalein test but none had nonprotein nitrogen retention. All of them showed grade 4 retinal changes, i. e. measurable edema of the optic disks in addition to other retinal vascular disturbances. Microscopically the diagnosis of malignant vascular nephritis is usually associated with necrotizing arteriolitis. In none of these 14 cases of so-called malignant hypertension nor in any of the remaining cases in the series was there any arteriolar necrosis. Our data thus substantiate Goldblatt's⁶ experimental evidence that both hypertension and severe renal insufficiency with uremia are necessary factors in producing necrotizing arteriolitis. He was able to produce these lesions in dogs by decreasing the blood supply of both kidneys below the level that was usually necessary to cause merely benign hypertension. These 14 patients were operated on before the onset of uremia and their kidneys, therefore, would not be likely to show any arteriolitis. Only

1 died postoperatively. Although it is not within the scope of this paper to discuss the value of sympathectomy, it is interesting to note that the 2 patients in this group who have been followed for over a year after sympathectomy now have blood pressures of 120/90 and 140/100. Their respective blood pressures before operation were 175/135 and 230/160.

FOLLOW-UP

Obviously great care is being taken to follow these patients. Our follow-up data at the present time in the individual renal biopsy groups are inadequate for us to attempt to predict which cases will respond to sympathectomy. However, it is of interest to report

Chart 1—Distribution of normal renal function among the renal biopsies

that to date data are available on 21 patients who have been followed for at least a year. Most of these are in grades 2 and 3 renal vascular disease and have responded well. For example, the 7 patients in grade 2 that have been followed for a year have all had a fall in blood pressure averaging 45 mm of mercury systolic and 20 mm diastolic. Ten out of 11 patients in grade 3 had falls in pressure averaging 70 mm systolic and 35 mm diastolic. Only 1 patient with grade 4 renal disease has been followed for a year. He is back at work and his pressure which was 212/144 preoperatively is now 160/100. The blood pressures of 2 patients with grade 1 renal disease have not changed appreciably. We have just recently had the opportunity of studying a second biopsy taken one year after the first from a woman aged 27, and although her blood pressure, which was 235/145 before splanchnic resection is now 150/100, the renal disease, which was classified as grade 3, has not changed.

COMMENT

The most striking result of this work is the finding of such a high percentage of renal biopsies in which there is no or only minimal vascular disease. Seven per cent were graded 0, 21 per cent grade 1 and 25 per cent grade 2, i. e., 28 per cent and possibly 53 per cent of the cases showed renal vascular systems so slightly damaged that it seems unlikely that the blood flow could have been embarrassed sufficiently to be the one factor responsible for the hypertension. A valid objection might be raised that a biopsy as small as the ones removed in this series is not an adequate sample of the whole kidney. We believe, however, that since great care was taken to select a representative region for biopsy and since similar morphologic findings were present in both kidneys in those 25 cases in which bilateral biopsies were taken, each biopsy is a fair sample of the renal tissue in the respective case. When the preliminary report of this work was presented before the American Association of Pathologists and Bac-

teriologists in April 1941,⁷ biopsies on only the first 16 cases were available. The statement was made then that all of the specimens showed definite and fairly severe vascular disease. In view of additional evidence it is apparent that this series was too small and included a high proportion of cases in which there was more severe hypertension. The biopsy grades of these 16 cases were 3 in grade 4, 11 in grade 3 and 2 in grade 2. It was our feeling at that time that since nearly all the biopsies showed moderate to severe vascular disease with relatively little if any renal impairment, perhaps the anatomic changes had probably antedated the hypertension. In the larger series of 100 patients, however, there were 53 who had normal kidneys or minimal renal vascular disease. Most of these patients, however, had had their hypertension for years and almost 30 per cent of them had hypertension which was clinically severe, some associated with cerebral hemorrhage or thrombosis.

The following is a case in point.

A housewife aged 38 developed mild hypertension 150/90 during the second trimester of her first pregnancy sixteen years before admission. Her blood pressure returned to normal following this pregnancy but rose again during her second pregnancy three years later. Ever since then she had had mild hypertension and during the past five years complained of fatigue, palpitation, dyspnea on exertion and occasional headaches. Examination four years before entry showed normal ocular fundi except for slight arterial constriction grade 1. The blood pressure was 170/110. There was no albuminuria. The heart was not enlarged. Two years later slight cardiac enlargement was demonstrable and there was a faint trace of albumin in the urine. Finally during the year before admission severe occipital headaches, increasing fatigue and nervousness developed. Her blood pressure was 260/150, the heart was large and the fundi showed 1 to 2 diopters of papilledema. The urea clearance was 92 per cent of normal.

Here, then, is a patient who had mild hypertension for many years and then suddenly so-called malignant

Chart 2—Average renal plasma flow values for each of the five grades of renal vascular disease

hypertension developed. Her renal biopsy showed only grade 1 changes—changes with luminal arteriolar narrowing so slight that under no circumstances could they alone be held responsible for the origin of the hyper-

7. Castleman, Benjamin, Smithwick, R. H. and Palmer, R. S. Renal Biopsies from Hypertensive Patients. *Abstracts from Scientific Proceedings of the 41st annual meeting of the American Association of Pathologists and Bacteriologists*. *Am J Path* 17: 617-619 (Dec.) 1941.

tension. It seems reasonable to infer therefore that her hypertension antedated her renal vascular disease. It is very probable that a renal biopsy performed a few years before would not have shown any vascular change.

This patient is one of the group of 21 (grade 1) having such minimal evidence of renal vascular disease that one is led to believe that the hypertensive state antedated the vascular disease. This possibility seems even more likely when one considers that 7 cases in this series, some with severe long-standing hypertension had no renal vascular disease at all (grade 0). It can further be stated that, in many of the 25 cases presenting grade 2 renal vascular disease in which the changes did not appear severe enough to have diminished the vascular bed to cause hypertension, the hypertension may also have antedated the vascular disease. This is in keeping with Cox and Dock's⁸ recent perfusion experiments on kidneys post mortem in which they found that "most kidneys from patients with hypertension without uremia have vascular beds in the normal range." In another paper² based on 20 of the cases reported here it has been shown that a correlation appears to exist between renal vascular disease and renal plasma flow. Chart 2 shows the average renal plasma flow values for each of the five grades of renal vascular disease. It is interesting to note that in the grade 0 and grade 1 renal

TABLE 4—Distribution of Peripheral Vascular Disease Found in Renal Biopsies

biopsy groups there was very little if any reduction in blood flow, in the grade 2 group there was a 25 per cent reduction, in the grade 3 group a 30 per cent reduction and in the grade 4 cases a 60 per cent reduction.

We are therefore led to the conclusion that a state of hypertension not infrequently exists in man in which evidence of renal vascular disease is either absent or is insufficient to explain the elevated blood pressure. The implication is that in many cases some other functional factor or factors exist which are primarily responsible for the hypertensive state and which precede the appearance of renal vascular disease. This point of view would appear to correspond to that of Homer Smith and his associates,⁹ who found evidence from renal blood flow studies "that there exists a perturbation of vascular function which is primary in time and causality to the destruction of renal parenchyma." It is certainly very probable that the vascular disease, once established, aggravates the already present hypertension, which in turn accelerates the arteriosclerosis—a vicious circle. This is the stage in which the kidney is found post mortem and on which the theory of the primary vascular origin of essential hypertension is based. Our observations of the kidney biopsies in the earlier stages of hypertension have given us the missing link to help substantiate the theory that the hypertensive state precedes the renal vascular disease in many cases.

Because of the fact that renal vascular disease of consequence is known to exist in some normotensive patients dying of various causes (12 per cent in Moritz and Oldt's series) it seems probable that renal vascular disease could have been present before the onset of hypertension in some cases. In other cases renal vascular disease may result from lesions of one or both kidneys such as pyelonephritis. Even so the conclusion that renal vascular disease is the sole cause of hypertension under these circumstances is open to question. Granting that renal vascular disease may be present before the onset of hypertension, our data suggest that in many cases of so-called essential hypertension the elevation of blood pressure precedes the development of vascular disease in the kidney. It is not our purpose to minimize the importance of the kidney as a factor in the hypertensive state. We believe that it is probably the most important of all splanchnic viscera once it becomes involved by vascular disease or by some other mechanism resulting in a reduction or modification of the nature of its blood flow. We simply wish to indicate that the following sequence of events not infrequently exists: (a) hypertension and (b) renal vascular disease.

Just when peripheral vascular disease enters this sequence has not yet been established. There has been so much difference of opinion in the literature as to whether peripheral arterioles are or are not diseased in cases of hypertension that a study of the arterioles in biopsies of the sacrospinalis muscle in relation to the renal biopsies has been begun. At the present time we have examined only one section of muscle from 46 of the 100 cases in this series and without resorting to micrometer measurements noted that medial hypertrophy was present in only 40 per cent of the cases. Table 4 shows the distribution of these changes in the renal biopsy groups.

It is interesting to note the rare presence (7 per cent) of peripheral arteriolar sclerosis in grade 1 renal disease and the apparent increase of peripheral vascular disease in the higher renal groups (60 per cent in grades 3 and 4). Since each section contained relatively few vessels and since peripheral arteriolar sclerosis may be segmental (Moritz and Oldt¹¹) it is quite possible that vascular disease may have been missed in some of the cases. Without serial sections of the blocks of tissue and perhaps micrometer measurements of the vessels no definite conclusions should be made from these findings. If these preliminary observations are confirmed it will be possible to conclude that the peripheral vascular disease develops after the renal disease.

SUMMARY AND CONCLUSIONS

1 Renal biopsies from 100 hypertensive patients in the course of splanchnic resections for hypertension were examined microscopically and the degree of their vascular disease divided into five grades as follows: grade 0, 7 per cent, grade 1, 21 per cent, grade 2, 25 per cent, grade 3, 33 per cent and grade 4, 14 per cent.

2 The patients averaged 39 years of age and were suffering from hypertension (average 210/130) for about six years. Sixty per cent had normal renal function as measured by the phenolsulfonphthalein test and all showed retinal vascular changes from mere arteriolar narrowing to edema with elevation of the optic disks.

3 In contrast to the almost invariable finding of well developed arteriolar disease in the kidneys of hypertensive patients observed post mortem, 28 per cent of the biopsies showed no or insignificant vascular disease and an additional 25 per cent only mild changes.

4 From these observations it is concluded that the morphologic evidence of renal vascular disease in more than half of the cases was inadequate to be the sole

factor in producing the hypertension and that in many of these and probably others the hypertensive state antedated the renal vascular lesion, which, once established, probably aggravated the hypertension. Furthermore, these observations are not in keeping with the concept that renal ischemia due to preexisting renal vascular disease is the cause of essential hypertension in man.

5 It is of interest to note that eight adrenal tumors were found in 7 patients. Six were cortical adenomas and two were pheochromocytomas. The latter had not provoked paroxysmal attacks of hypertension.

THE ADMINISTRATION OF EGG WHITE AND AVIDIN CONCENTRATES TO PATIENTS WITH CANCER

C. P. RHOADS, M.D.
AND
JULES C. ABELS, M.D.
NEW YORK

A rational basis for the treatment of cancer is to deprive the neoplastic tissue of the components required for its growth. This basis presumes that neoplastic cells either contain certain constituents lacked by their normal analogues or that the requirement for those constituents by the cancer tissue is greater than that of normal tissue.

Recently, several types of carcinoma were reported to contain abnormally high concentrations of biotin.¹ About the same time it was noted that the addition of biotin to diets which prevented in rats the development of hepatomas induced by the feeding of butter yellow broke down the protection those diets otherwise afforded.² These observations do not necessarily imply that biotin is required for the induction or growth of neoplastic tissue. They do suggest the possibility, however, that, if biotin should be withheld from patients bearing cancer, the growth of the neoplasm might be decreased to a greater extent than would that of the normal tissues.

The existence in egg white of a protein, avidin,³ which forms a complex with biotin has been known for several years. The oral administration of large amounts of dried egg white to rats induces in them a deficiency syndrome presumably because the avidin prevents the absorption of dietary biotin from the gastrointestinal tract.⁴ The production of a biotin deficiency in man also has been claimed. Clinical evidence of this deficiency was obtained within four to twelve weeks in normal individuals maintained on low biotin diets supplemented with about 1,000 units of avidin in the form of crude egg white. At the same time as clinical changes appeared, the urine of the subjects possessed abnormally small amounts of biotin activity.⁵

Obviously, the next step was to induce by the administration of egg white a biotin deficiency in patients with cancer and thereby to deprive the neoplastic tissue of a component possibly required in greater amounts by the tumor cells than by the normal cells. Accordingly, 2 patients with widespread cancer were given diets low in their content of biotin and supplemented with amounts of avidin several times greater than that necessary to bind *in vitro* the dietary biotin. The results obtained form the subject of the present communication.

CLINICAL MATERIAL

The first of the 2 patients studied was L. W., a woman aged 58 with a mammary carcinoma of grade 2. A mass in her right breast first was noted ten years before admission to the hospital. The existence of the mass had been neglected and it had been allowed to grow until the whole breast was replaced by an ulcerating tumor. This extended through the chest wall on to the right pleura with metastases to the liver and to the right axillary and supraclavicular nodes. X-ray examination failed to reveal intrapulmonary or bone metastases but did demonstrate the existence of a moderate right pleural effusion. Accordingly the patient was considered to be unsuitable for surgery or radiation therapy.

The second patient, H. M., a man aged 48 with chronic lymphatic leukemia, for four months had noticed a gradual, progressive weakness, pallor, anorexia, generalized lymphadenopathy and abdominal distention. On admission he was found to have decidedly enlarged lymph nodes in all areas, the liver edge extended to the level of the umbilicus and to the midline, the spleen extended 2 inches below the umbilicus and also to the midline. There was a moderate degree of ascites, peripheral edema, dilated abdominal veins and bone tenderness. His red cell count was 2,033, hemoglobin 35 per cent and white cells 420,000, of which 98 per cent were adult lymphocytes. A sternal marrow aspiration confirmed the diagnosis of chronic lymphatic leukemia.

Throughout the present study, neither patient received any x-radiation therapy.

METHODS

The method used for the assay of avidin³ in the egg white and of biotin⁶ in the diet and in the urine of the patients was essentially that of Snell and others.⁷ The following modifications were employed:

(a) The Fleischmann foil yeast cake was used. Under the experimental conditions employed, the effects of biotin on the growth rate of this organism were the same as on the yeast used by Snell and his collaborators.

(b) To prepare a urine for its determination of biotin, a 5 cc sample was made acid with 12 normal sulfuric acid and autoclaved at 15 pounds pressure for one hour. The pH of the autoclaved urine was adjusted to 4.2 by the addition first of potassium hydroxide 1:1 and then of potassium hydroxide N/1. A glass electrode was employed for the titration. The urine specimen then was diluted with water to from 200 to 500 volumes and 0.25, 0.5, 1.0 and 2.0 volume samples used for assay.

(c) To assay the biotin content of the diet, amounts of all the foods equal to those ingested in the course of a day (other than egg white) were combined in a

6 Throughout this communication the term "biotin" is used to indicate the yeast growth effect in the assayed materials in terms of biotin equivalents.

5 liter jar. Water was added to make 1 liter, and the whole was thoroughly mixed for two hours by an electric stirrer. Three aliquots (5 cc) of this mixture then were removed for analysis. Each sample was acidified with 9 volumes of 6 normal hydrochloric acid and autoclaved at 15 pounds for one hour, the pH of the

excreted daily in the urine of patient 1 ranged from 6 to 132 micrograms and averaged 37 micrograms (chart 1). Thus it would appear that the addition of about sixteen times the amount of avidin to bind in vitro the biotin in the diet of this patient with mammary cancer did not decrease the urinary biotin excretion. The urine of patient 2, the man with leukemia, was not collected during this period.

The clinical condition of neither patient during the first twelve weeks of avidin ingestion was altered significantly from that expected. The ulcerated breast carcinoma of patient 1 had extended, she lost weight and bone metastases had occurred. The patient with leukemia became progressively anemic and required several transfusions. His white cell count fluctuated between 200,000 and 700,000 of which from 98 to 100 per cent were adult lymphocytes. No decrease in the size of his lymph nodes, liver or spleen were noted, but the ascites and peripheral edema did subside. However, this decrease of extravascular fluid probably was due to bed rest and a restricted fluid intake (1,500 cc. a day). In neither patient did any of the signs and symptoms attributed to a biotin deficiency appear, namely desquamative macular dermatitis, shiny gray pallor, papillary atrophy of the tongue, mental changes, hyperesthesia, paresthesias, anorexia or nausea.

At the end of the twelfth week of egg white supplements the administration of avidin to both patients was increased by the addition of from 500 to 750 units of

Chart 1—The ingestion of biotin and avidin and the urinary excretion of biotin active material by a patient with cancer of the breast

autoclaved mixture was adjusted to 4.2 as previously described and the specimen diluted to 500 cc. 1/10, 0.25, 0.5, 1.0 and 2.0 cc samples were used for analysis.

Both of the patients were maintained on dietary regimens designed to induce, if possible, a biotin deficiency. When first admitted, each was given a diet which consisted each day of milk 1,150 cc, white bread 80 Gm, washed butter 30 Gm, farina 200 Gm, sucrose 50 Gm, saltine crackers 40 Gm and lean beef 60 Gm. By analysis this diet was found to contain 60 micrograms of biotin. Supplements of 5,000 units of vitamin A, 10 mg of thiamine, 200 mg of ascorbic acid, 500 units of vitamin D, 6.25 mg of calcium pantothenate, 6.25 mg of pyridoxine and 180 mg of ferrous sulfate were added. This diet was given to patient 1 for two weeks without the addition of avidin during which time her urinary biotin excretion ranged from 24 to 36 micrograms and averaged 27 micrograms a day.

After a two weeks basal period in case 1 and immediately in case 2, from 1,000 to 1,200 units of avidin was added daily to their diets. The avidin was supplied in the form of about 375 Gm of raw frozen egg white and 165 Gm of dried egg white. The avidin content of this raw material was found here to be 0.5 unit per gram, and that of the dried egg white from 4.0 to 5.0 units per gram. The egg white fractions either were mixed with milk or else whipped and spread on soda crackers.

RESULTS

The administration of the avidin supplements to both patients was continued for thirty weeks. In the first twelve weeks of that period the amounts of biotin

Chart 2—The ingestion of biotin and avidin and the urinary excretion of biotin active material by a patient with chronic lymphatic leukemia

concentrated material⁸ during the next sixteen weeks and by 1,000 to 1,250 units for the last two weeks of the experiment.

At this time the original diet was replaced by more palatable foods. The composition of the revised diet

⁸ Prepared and supplied through the courtesy of Dr. Vincent du Vigneaud and Mr. K. Dittmer, Cornell Medical College, New York City, who gave counsel and many helpful suggestions throughout the course of this investigation.

(described in the table) by analysis was found to contain 46 micrograms of biotin. The vitamin and non supplements were continued throughout the remaining eighteen weeks of the experiment. In that period neither patient manifested any evidence of biotin deficiency. Moreover in neither instance was a decreased urinary excretion of biotin noted. Patient 1 excreted from 15 to 270 micrograms a day (average 95 micrograms a day) during the last eighteen weeks of avidin administration (chart 1). Likewise patient 2 excreted from 21 to 70 micrograms (average 38 micrograms a day) during his last thirteen weeks of avidin intake (chart 2).

Thirty weeks after the avidin therapy was first instituted the experiment was discontinued. The patient with cancer of the breast had developed intrapulmonary metastases, considerable pleural effusion and increased hepatomegaly. She finally died four weeks after the experiment was completed. The patient with lymphatic leukemia still had pronounced hepatosplenomegaly, lymphadenopathy, anemia and leukocytosis. He was treated finally by x-radiation, which induced a considerable decrease in his white cell count and lymphadenopathy.

COMMENT

The administration of from sixteen to forty times the amounts of avidin necessary to bind *in vitro* the biotin ingested by the 2 patients studied apparently had no effect on the course of their neoplastic disorders. Neither subject developed the clinical syndrome attributed to a lack of biotin or excreted less of that vitamin in the urine than before avidin was administered. Accordingly, these observations would suggest that the measures used were inadequate to induce the biotin deficiency syndrome described in animals and in normal human beings. Either the ratio of ingested avidin to biotin necessary to establish a clinical biotin deficiency or to decrease the urinary excretion of biotin is considerably greater than that used in the present investigation, or the avidin-biotin complex was broken down during the process of digestion so that a biotin deficiency could not be produced. In any event, to be satisfied that the administration of avidin had no effect in the growth of the cancer it would be necessary to establish in patients with malignant neoplasms clinical and experimental evidence for the existence of a biotin deficient state.

It is to be noted that patient 1 excreted more biotin in her urine than she received in her diet despite the simultaneous ingestion of large amounts of avidin. This anomalous situation likewise was observed by Oppel⁹ in certain normal individuals who received amounts of egg white sufficient to bind their dietary biotin. On the other hand, the possibility exists that the biotin of the egg white and avidin concentrates administered in the present investigation were liberated by the enzymes of the foods in the diet or in the gastrointestinal tract.

In studies from this laboratory it was found that the growth of spontaneous mammary carcinoma in eight strains of mice was not affected when a typical biotin deficiency was induced in them. Also the growth of sarcoma 180 was not influenced by this dietary regimen.¹⁰ Moreover, the inoculation of fragments of sarcoma 37 or sarcoma 180 into mice already in a biotin deficient state was followed by a tumor growth at the

expected rapid rate.¹¹ These observations accordingly indicate that, at least in mice, no relation could be established between the existence of biotin deficiency and tumor growth.

The failure to alter the course of the neoplastic disorders in the patients studied does not mean necessarily that the oral administration of egg white and avidin will prove to be valueless in the treatment of patients with cancer. The present investigation included only 2 persons each with a different neoplastic disorder. The effects of similar treatment of other patients with these or other forms of cancer are unknown. Moreover the long continued administration of large amounts of egg white and avidin concentrates to subjects on a constant diet apparently does not decrease their urinary excretion of biotin and evidently the mere feeding of large avidin supplements is not sufficient to produce clinical or experimental evidence of biotin deficiency in man.

CONCLUSIONS

1 One patient bearing mammary cancer and 1 with lymphatic leukemia were fed for thirty weeks from sixteen to forty times the amounts of avidin necessary to bind *in vitro* the limited amounts of biotin in their diets.

2 No clinical evidence of biotin deficiency was induced in these subjects nor were the amounts of biotin excreted in their urine abnormally low.

3 No effect was noted on the expected clinical course of these patients.

Potatoes and Potassium—Among various foods the potato has the highest potassium content. 55 Gm of potassium in 2 pounds of potatoes. Potassium is a dangerous poison when injected directly into the blood and, considered objectively, potatoes are more poisonous than wine or coffee. If the potassium contained in an ordinary portion of potatoes was injected into the blood stream it could kill a man. But it never reaches the blood. A large part remains with the cellulose in the intestine and leaves the body in an indigested state. The assimilated potassium is stored in the liver and released into the blood only in the same minimal quantities in which it is excreted by the kidneys at the other end of the circulation.—Kahn, Fritz. *Man in Structure and Function* volume 2 translated from the German and edited by George Rosen M.D., New York, Alfred A. Knopf, 1943.

FRANCISCO R TIANT, M D

HAVANA, CUBA

Leprosy affects the skin, the peripheral nervous system and the mucous membrane of the nose by preference, but other tissues and organs are also affected, often early in the disease, such as the testicles, the mammary glands, the lymphatic glands, the larynx and the eyes. Late manifestations of the liver, spleen and other internal organs may occur.

Lesions of the muscles, bones, skin, hair, nails and mucous membranes may not be directly due to the presence of *Mycobacterium leprae* but to trophic disturbances caused by nerve involvement.

The Correlation of the Pathology, Immunology and Bacteriology of Leprosy

	Pathology	Immunology Lepromin test	Bacteriology	
Leprosy of the skin	Lepromatous	Negative	Numerous bacilli	
	Tuberculoid	Milliary	Positive	Rare bacilli
		Sarcoidal	Positive	Rare bacilli
		Lazarine	Positive	Abundant bacilli in necrotic areas rare in tissues
	Nonspecific	Erythematous	Pos or Neg 50%	Few bacilli
		Pigmented	Pos or Neg 50%	Few bacilli
		Achromic	Pos or Neg 50%	Few bacilli
Leprosy of the nerves	Lepromatous	Negative	Numerous bacilli	
	Tuberculoid	Milliary	Positive	Rare bacilli
		Colligative		
	Nonspecific	Pos or Neg 50%	Few bacilli	
Leprosy of other tissues and organs	Lepromatous	Negative	Numerous bacilli	
	Tuberculoid	Milliary	Positive	Rare bacilli
		Sarcoidal		
	Nonspecific ?	?	?	

The preference of leprosy for the skin and peripheral nerves led to the classic conception of "cutaneous," "neural" and "mixed" types of leprosy. However, it is evident that the great majority of patients with leprosy present symptoms and signs of cutaneous, neural and visceral involvement and therefore most cases of leprosy would fall under the heading of "mixed leprosy."

On the other hand, the fact that the clinical manifestations of leprosy affect the skin, the peripheral nervous system and many other tissues and organs does not offer a definite foundation for the classification of the types of leprosy, especially as to their prognosis, epidemiology, pathology and immunology. Cutaneous lesions may be severe and of bad prognosis or may be slight and of good prognosis. Nerve involvement may

be slight and chronic without much loss of function or may be severe, leading to rapid wasting and complete disability.

The leprosy congresses of Manila¹ in 1931 and of Cairo² in 1938 considered the classification of the clinical forms of leprosy, adhering to the old ideas and preserving the cutaneous, neural and mixed types. However, the South American dermatologists insist on the advisability of using a pathologic foundation for the classification of leprosy following the suggestion made as early as 1936 by Eduardo Rabello Jr.³ of Rio de Janeiro. This classification has been adopted by the South American dermatologists, among whom the contributions of the Rabellos,⁴ Schujman, N. V. Greco,⁵ Souza Lima,⁶ Moura Costa,⁷ Aguirre Pupo⁸ and Bahía and Bassombrio,¹⁰ are prominent.

The pathologic changes found in leprosy are sufficiently definite and characteristic, corresponding with clearcut clinical aspects in the great majority of cases and with definite immunologic reactions and bacteriologic findings, making the correlation of these factors most important from the points of view of the prognosis and the sanitary control of the disease.

Whether leprosy affects the skin, the nervous system or the other tissues and organs, the pathologic changes may be grouped in three categories: lepromatous, tuberculoid and simple inflammatory, which we shall call nonspecific. To the trained eye these pathologic changes have clinical equivalents: the lepromatous, represented by the nodular infiltrative lesions; the tuberculoid, represented by flat infiltrated annular or ringlike small nodular lesions; and the nonspecific, represented by the nodular manifestations of the skin and the simple dystrophic neural manifestations.

The fact that lepromatous lesions are extremely rich in Hansen bacilli, while the tuberculoid and nonspecific are paucibacillary and that the immunologic lepromin tests are negative in lepromatous and positive in tuberculoid types adds strength to the practical importance of this classification.

The lepromatous and tuberculoid types are therefore definite clinical, pathologic, bacteriologic and immunologic forms of leprosy. The nonspecific types represent transitional stages and these cases may remain nonspecific for a long time or may develop into lepromatous cases or into tuberculoid cases. The tissues show only perivascular inflammation with lymphocytic infiltration. In some cases a few bacilli are scattered in the tissues or are demonstrable in the lymph and mucous membranes, while in others few or rare bacilli are found. In 40 to 60 per cent of these nonspecific types the lepromin test is positive while in the other 40 to 60 per cent the lepromin test is negative. Therefore the nonspecific types may progress to the severe lepromatous manifestations or slowly develop the more benign tuberculoid symptoms.

Read before the Section on Dermatology and Syphilology at the Ninety Third Annual Session of the American Medical Association, Atlantic City, N. J., June 10, 1942.

The accompanying table resumes the South American classification of leprosy modified by us, to make the clinical aspects more prominent and adding the lezantine type of tuberculoid leprosy

THE LEPROMATOUS TYPES

When *Mycobacterium leprae* invades the skin, mucous membranes, peripheral nerves and other tissues and organs, finding little or no defensive reaction, the histologic features are those of a chronic infiltrating granuloma affecting the totality of the tissue. The cells are large histiocytes with special characteristics, some are vacuolated and badly stained and some are huge cells filled with mucous degenerated protoplasm and innumerable accumulations of acid fast bacilli. The connective and elastic tissue disappear entirely and are supplanted by the cellular infiltrate. The glands and hair follicles are gradually choked and finally atrophy.

These infiltrations appear clinically as nodular formations more or less lobulated, usually dark red, well defined from the adjacent parts and varying in diameter from a few millimeters to several centimeters. Others are diffuse infiltrations without definite outline, more or less flat and geographic in outline. In the peripheral nerves the infiltrations may be total, thickening the nerves to three or more times their normal size, or may be moniliform, like the beads of a large rosary along the trunk of the nerve. In other tissues such as the testicle and mammary gland the lepromas affect the form of hard nodules, absolutely painless and without apparent signs of inflammation. In the larynx, nose and other mucous membranes the lesions ulcerate early, and deformities and mutilations are extreme. In advanced cases lesions of the liver and other internal organs present the same diffuse lepromatous infiltrations or localized nodular formations.

This is the easiest type to diagnose, and the cutaneous lesions may be recognized even by the layman in countries where leprosy is common.

Bacteriologically the lepromatous lesions are so full of acid fast bacilli that in the tissues they may be seen with the small dry objective in the form of bright red patches spread throughout the microscopic field. Two methods may be employed to examine tissues for bacteriologic diagnosis: one may remove a piece of a leproma by means of small curved scissors, imprinting the tissue juices on several cover slides, or make a small incision in the mass of the leproma, scraping off the soft tissues in the bottom of the wound with the scalpel and spreading the juice thus obtained on a cover slide. When proper staining is done by the Ziehl-Neelsen method, the number of acid fast bacilli in these preparations is enormous. It must be remarked that the specimens obtained from the mucous membranes of the nose should be taken by scraping the mucosa as deeply as possible without causing hemorrhage.

Immunologically lepromatous types show absolutely no reaction when tested with lepromin. Sometimes an early nonspecific reaction appears after the first or second day but disappears without leaving any trace. This absence of allergic response to lepromin means that the patient offers no defense to the infection. Therefore the prognosis of these cases is bad.

From a prophylactic point of view lepromatous cases are dangerous, being open and literally oozing *Mycobacterium leprae* of the highest virulence. These are the cases that must be isolated from the community.

THE TUBERCULOID TYPES

The tuberculoid types show three different histopathologic variations: the typical miliary type with giant cells, the sarcoidal type with circumscribed collections of histiocytes of the foamy type in the form of round, oval or sausage shaped nests and a third type with peculiar features ending in necrosis, which we have described as 'lezantine leprosy'.¹¹ In the peripheral nerves the histologic changes are similar and there is a particular type reported by Eduardo Rabello Jr.¹² as "nodular colligative neuritis" in which necrosis and abscess formation are the main features together with typical tuberculoid follicular structure. This last mentioned type may possibly be the neural equivalent of the "lezantine leprosy" of the skin.

Eduardo Rabello Jr.¹³ has described tuberculoid changes of the sarcoidal variety in the lymphatic glands and bones, a syndrome difficult to differentiate from lymphogranulomatosis benigna or Besnier-Boeck-Schaumann disease.

Clinically the tuberculoid lesions of the skin and peripheral nerves may be diagnosed by the expert. As a rule the lesions are few in number, sharply circumscribed, erythematous patches or flat infiltrations, often ring shaped or festooned, with macular center and elevated border, the latter being uniform or composed of small nodules arranged side by side.

Sometimes the lesions, which are first infiltrated and elevated patches of vivid red or purple, suffer a process of involution in the center and become atrophic with a ringlike border. The nerves more often affected are those of the upper extremities, particularly the ulnar, and also the superficial auricular branch of the cervical plexus. They appear as thick, pencil-like lineal infiltrations under the skin but show no discoloration. The ulnar nerve may be palpated in the ulnar canal at the inner part of the elbow as a thick or moniliform cord. In the type described by Eduardo Rabello Jr., of which we have seen only 1 case, the painless abscess forms in the mass of the ulnar nerve and progresses toward the skin, adhering to the latter and finally causing superficial necrosis and ulceration.

Bacteriologically the lesions of tuberculoid leprosy show very few acid fast bacilli. Often only one or two bacilli may be seen in a whole section of skin or nerve after painstaking search. Often no bacilli at all can be demonstrated, either in the sections or in the lymph tissue scrapings or mucous membrane secretions.

Immunologically the tuberculoid types of leprosy show the maximum possible allergy of the skin in the form of strongly positive lepromin tests, varying from the nodular to the necrotic. This is a constant feature which shows the excellent defenses of the body and proves once more the law of Jadassohn-Lewandowsky.

From a prophylactic point of view, persons with tuberculoid leprosy are not dangerous and in some countries where leprosy is endemic these patients are not isolated but are allowed to remain at home under sanitary supervision. Some leprologists contend that these patients should not be treated but allowed to develop their immune reactions spontaneously.

In 'lazarine leprosy' the clinical lesions consist of plaques of cutaneous gangrene developing at the site of bullae, these necrotic manifestations are few in number but extremely destructive, causing deep, foul ulcers usually in the extremities which disorganize the muscles, tendons and joints. These ulcers are painless and as a rule heal leaving irregular scars in which there is absence of thermic and painful sensations. Recurrent crops of bullae may occur after healing. These are the only clinical manifestations there being no other cutaneous or neural lesions of tuberculoid type. The peculiar feature of this type of tuberculoid leprosy is that in spite of the tuberculoid structure of the affected tissue the gangrenous parts and the contents of the bullae are extremely rich in Hansen bacilli but not the tissue. The lepromin test is strongly positive, showing a high allergic reaction indicative of excellent defenses. In our opinion the 'lazarine' type of leprosy is the result of a massive infection with Hansen bacilli of patients with high immunologic defenses and the clinical symptoms represent the typical Koch phenomenon, with the throwing off of huge numbers of Hansen bacilli by the defensive mechanism of the body. Lazarine leprosy although highly destructive is of good prognosis and most patients recover spontaneously.

THE NONSPECIFIC TYPES

Clinically the nonspecific types of leprosy are characterized by the presence of macular erythematous, ichthymic or pigmented skin lesions and by slight enlargement of the peripheral nerves with areas of apparently healthy skin in which the thermic and painful sensations are abolished. These types are at times exclusively neural and then the sole manifestations may be those due to trophic disturbances, such as areas of anesthesia, muscular atrophies, retraction of the fingers and toes, paralysis of the muscles of the face, bone resorptions, mal perforans plantaris disturbances of the sweat and sebaceous secretions and filling of the hair. More often neural disturbances and cutaneous erythematous or dyschromic lesions are present together. Pathologically the tissues show only perivascular and perineural simple inflammatory changes consisting of cuffs of lymphocytes around the larger vessels of the upper cutis or the small trunks of the cutaneous nerves. In the cutaneous dyschromic or erythematous manifestations often called 'leprids' there is also pronounced vascular dilatation and passive congestion. The basal cells are often devoid of pigment, and chromatophores may be very abundant on the upper cutis in the pigmented lesions.

Bacteriologically these lesions, whether of the skin or of the nerves, are poor in acid bacilli. As a rule direct examinations of lymph result in negative findings.

The lepromin test is negative in some cases and positive in others, about 50 per cent of each although some investigators claim the numbers of positives much higher.

In reality cases of 'nonspecific' leprosy are transitional types, some of which progress toward the 'lepromatous' type and others toward the 'tuberculoid' types. At times the transition is quite rapid, and a patient who showed only macular lesions will suddenly develop crops of lepromas in an acute outbreak of 'lepra reaction'.

The prognosis of these transitional types may be foretold by the results of the lepromin test. Those who show positive tests will probably remain as non-

specific types or will develop tuberculoid lesions. Those showing a negative lepromin reaction will in all probability develop lepromatous lesions.

THE MIXED TYPES

These transitions naturally result in types in which both lepromatous or tuberculoid and nonspecific 'leprids' coexist until the patient finally develops the definite type which the disease will follow in his particular case. Therefore in these cases the presence of leproma establishes the type as 'lepromatous' in spite of the presence of numerous erythematous or dyschromic lesions. Likewise the presence of tuberculoid lesions establishes the type as 'tuberculoid' in spite of the presence of erythematous or dyschromic manifestations. In many cases the clinical appraisal may be difficult and resort must be had to pathologic and bacteriologic examinations and even to the lepromin test in order to classify a case in the proper type.

The presence of lepromatous and tuberculoid lesions in the same patient has not been observed by us. The transformation of a lepromatous type into a tuberculoid type or vice versa has been reported by several investigators but we have not seen this phenomenon.

LEPRA REACTION

In sharp contrast with the usual slow and insidious evolution of leprosy there is sometimes observed an acute inflammatory phase which very frequently interrupts its chronic course or is the first clinical manifestation of the disease.

The major characteristic of the lepra reaction is its acuteness more or less accentuated in different cases. It is probably a manifestation of allergy or hypersensitivity of the body to the pathogenic agent. Sometimes the outbreak of the lepra reaction can be ascribed to a definite cause complicating diseases, alimentary or alcoholic excesses, too intensive antileprotic treatment and so on. Frequently it is impossible to determine its cause. The clinical picture and evolution of lepra reaction differ in lepromatous and tuberculoid cases.

In lepromatous leprosy it generally begins suddenly with fever (39 to 40 C. or 102.2 to 104 F.), rigors, myalgias, headache or prostration, followed in several hours by eruption of erythema multiforme or erythema nodosum type and the exacerbation of pre-existing lesions. In some cases there are extracutaneous symptoms: adenitis, orchitis, splenic and hepatic enlargement, neuritis and keratitis. The fever, of remitting type, and the other symptoms persist during several days, ten to fifteen, rarely more, and then disappear in lysis. Relapses are frequent. The lepromin test is negative. The erythrocyte sedimentation index is greatly augmented. Short, acute reactions are of good prognostic significance.

Long or relapsing reactions aggravate the course of leprosy.

The first therapeutic measure is the cessation of all antileprotic treatment and the administration of a mild saline laxative and a bland diet.

Injections of antimony and potassium tartrate 1 per cent solution, calcium salts, vitamin B₁ and diphtheria toxoid are useful agents.

Exacerbations in tuberculoid leprosy are not accompanied by any general symptoms or fever. They are characterized by the turgescence of pre-existing lesions, the appearance of new wine red, infiltrated patches

mostly located on the face and extremities by a protracted course, never less than three months, and frequently more than a year in length. The lepromin test is positive. The erythro sedimentation index is always low and prognosis is always good.

THE HISTAMINE TEST

The early manifestations of leprosy of the nonspecific or simple inflammatory type may be difficult to diagnose, although, if thermal and pain anesthesia are present, matters are simplified. However, many patients especially children, do not cooperate or they find it difficult to express their sensations, in which event the performance of the "histamine test" is very valuable.

When a drop of a 1:1,000 solution of a histamine salt is placed on the normal skin and a needle prick is made through the liquid a small wheal surrounded by an erythematous halo develops within a few seconds and persists for five minutes or more. When the sensitive nerve endings are paralyzed or destroyed the phenomenon occurs as far as whealing, but no erythematous halo develops around the wheal. The normal response to histamine is called the "positive test", the absence of erythematous reaction around the wheal characterizes the "negative test". Therefore in the cutaneous lesions of leprosy the histamine test is always negative. We have found occasion to do this test in numerous cases in which erythematous or dischromic lesions were suspected of being early manifestations of leprosy. The superficial, erythematonodular cutaneous syphilids have been the subject of differential diagnosis with early lesions of leprosy in several cases, and in these the "histamine test" has proved of definite help. The serologic reactions may be positive in the presence of leprosy, and the changes in cutaneous sensations may be difficult to appraise when patients are not cooperative.

THE LEPRONIN TEST (MITSUDA REACTION)

The lepromin test consists essentially in the intradermal injection of an antigen prepared from lepromatous tissues rich in Hansen bacilli.

Skin tests in leprosy were originally intended to find a diagnostic procedure similar to the tuberculin test in tuberculosis. No results were obtained in this direction, and investigations were given up until 1923, when Mitsuda¹⁴ reported that, when an emulsion prepared with lepromatous skin was inoculated, healthy persons gave positive results, maculoanesthetic patients presented a late, nodular persistent inflammation and tuberous patients gave a negative local reaction. He deduced from his experiences that persons without leprosy and maculoanesthetic patients had a special immunity to the infection, while tuberous patients had no immunity. These findings and conclusions were later fully confirmed by many investigators.

All attempts to consider the test of any value in diagnosis are definitely abandoned. Its great importance in the classification of cases of leprosy and its immunitary and prognostic value are actually recognized by all.

Lepromin is prepared by boiling lepromatous tissues in isotonic solution of sodium chloride for one hour. The mass is then ground up in a mortar and 20 cc of isotonic solution of sodium chloride is added for each gram of ground up tissue. After thorough mixing and grinding again, the supernatant fluid is pipetted off,

filtered through gauze and stored in a sterile container, the remaining tissue being discarded.¹⁵

The liquid is autoclaved at 120°C for fifteen minutes, phenolized at 0.5 per cent and distributed in insulin type vials ready for use. It is a cloudy, milky emulsion containing numerous bacilli and globi plus all the tissue elements of the leproma. Kept in a dark cool place, it retains its activity for a long time. No easy standardization of lepromin is possible, being as it is such a complex suspension of bacilli and tissue material, but this does not interfere with the accuracy of results as wide variations in the concentration of the antigen do not give correspondingly different reactions. A nonreacting patient to the usual lepromin will not react to an antigen two or three times stronger. A reacting patient will do so to dilutions as high as 1:3,000 of lepromin, although with less intensity.

The presence of bacilli is essential to the activity of lepromin. Filtered antigens are inactive. Lepromins

Positive lepromin test twenty eight days after inoculation with 0.1 cc of lepromin intradermally.

prepared with tuberculoid tissues (paucibacillary) produce attenuated reactions and then only in patients with strong reactions to the usual lepromin. Antigens prepared with normal skin are inactive.

The test is performed by injecting into the cutis 0.1 cc of lepromin. The most common sites used are the arms, the dorsum and the anterior surface of the thigh. At the end of twenty-four to forty-eight hours an erythematous halo may be observed with at times some infiltration, but these manifestations disappear quickly, usually after the fifth day, leaving a dark brown discoloration and some wrinkling of the skin. On the seventh to the tenth day a small papule begins to form in the positive cases, gradually increasing in size and reaching its acme about the third to the fourth week, when it may be a nodule of as much as 1 cm in diameter. Occasionally the center sloughs off and a small ulcer

14 Mitsuda K. *Troisième Conférence internationale de la lèpre*. Communications et Débat. Paris: J. P. Baillière et Fils 1924: p. 219.

15 Rothberg A. Some Aspects of Immunity in Leprosy and Their Importance in Epidemiology, Pathogenesis and Classification of Form of the Disease. *Rev. brasil de leprol* 5: 45 (special number) 1937.

forms which requires several weeks to heal. In most cases the nodule regresses gradually after the fourth week, but in some cases of positive reaction some scarring is left. Rarely a positive reaction may not show until the third or fourth week and then follow the usual regressive course.

The erythematous reaction of the first few days is considered nonspecific. The reading of the test should be done about the thirtieth day after the intradermal injection. If there is no reaction or only a small (less than 5 mm) infiltration the test is negative. A well formed nodule more than 5 mm in diameter with or without a necrotic center characterizes the positive test.

Microscopic examination when the Mitsuda reaction is positive shows in specimens removed at its acme a collection of histiocytes, lymphocytes and at times giant cells, with an aspect very similar to that of tubercloid leprosy. In specimens removed forty-eight hours after inoculation acute inflammatory phenomena may be observed without any specific changes, but in some of our specimens a decided perivascular histiocytic infiltration was present, resembling even at this early date the tissue changes of tubercloid leprosy. However, we do not believe this is of diagnostic significance, as we have observed similar changes in lepromin tests of forty-eight hours' duration which later proved to be negative. The injected bacilli are not demonstrable in the lepromin reacting tissues. In negative tests, after the initial inflammatory reaction biopsies performed after eight, fifteen and twenty-eight days showed a return of the tissues to normal.

COMMENT

1. The classification of the types of leprosy on a histopathologic foundation into "lepromatous," "tubercloid" and "nonspecific" is the result of studies made by dermatologists of Brazil and Argentina and accepted by Latin American dermatology. In this article an attempt is made to correlate these pathologic forms with the clinical, immunologic, bacteriologic and public health aspects of the disease.

The lepromin test is given an important place among the immunologic reactions of the skin and reports are made based on many tests performed by the authors, corroborating for the most part the findings of other investigators.

The histamine test is studied as a diagnostic procedure in early cases of leprosy with lesions of the "nonspecific" type.

Consulado 9

ABSTRACT OF DISCUSSION

DR. HOWARD FOX, New York. The authors have done well to call attention to three phases of leprosy which are apparently not well known to American dermatologists. Little is said about them in American textbooks on dermatology or even in books on tropical medicine. I refer to the South American classification, the lepromin reaction and the histamine test. The classification of leprosy adopted at the Memorial Conference in Manila in 1931 divided the types of the disease into cutaneous, neural and mixed. They used the symbols C and N, adding the numbers 1, 2 or 3 according to the severity of the individual case. This classification was not satisfactory as the cutaneous lesions are of two entirely different types. One of them long known as nodular, represents a severe and usually fatal type, whereas the maculoanesthetic and the tubercloid lesions represent a relatively benign type and are invariably seen in neural leprosy. An improvement in classification was made at the International Congress of Leprosy in Cairo in 1938 by changing the term cutaneous to lepromatous and by including as subtypes of neural leprosy the pure anesthetic, the maculoanesthetic and the tubercloid forms. The classification adopted by South

American leprologists, while not as simple as those aforementioned, has the advantage, as the authors say, of correlating the clinical appearance of the disease with the pathologic, bacteriologic and immunologic changes. The nonspecific group is convenient, as one is at times doubtful as to whether macules are forerunners of the lepromatous type or of the relatively benign neural type of the disease. In such cases it may be impossible to settle the question by either microscopic or bacteriologic examination, but this can be done by the lepromin test. Tubercloid leprosy, first described by Jadassohn, is invariably associated with the neural type of the disease. It shows a tubercloid structure histologically with few if any, bacilli and gives a positive lepromin reaction indicative of comparative immunity to the bacilli. This type may often be recognized from the clinical appearance alone, the lesions being sharply defined more or less asymmetrical and often bright red. Some of them appear as large coin to palm sized yellowish, slightly thickened patches often with a mammillated surface. Others appear as diffuse, slightly thickened areas with a raised border and a tendency to form circles or portions of circles. The so called *hazrine* type of leprosy, which the authors have added to the South American classification is a rare manifestation, the only examples which I have seen being those which Dr. Pardo Castello demonstrated at the meeting of the American Dermatological Association in Havana in 1932. Curiously enough in spite of the destructive character of the lesions the lepromin reaction is always positive which indicates a good prognosis as to life.

DR. MARION B. STUBBERG, New York. Drs. Castello and Tiant give an insight into the immunologic biologic relationships in leprosy with a degree of clarity never previously offered to an American audience. The immunologic biologic factors in leprosy were studied first and most extensively by Josef Jadassohn while in Berne, Switzerland. There is an endemic focus of leprosy in Switzerland in several extremely isolated valleys of the canton of Valais. Few physicians from the outer world have penetrated into these valleys. At the time of Jadassohn's investigation leprosy had been in existence in these valleys for many generations. The peculiar thing is that leprosy has never disseminated from that focus to anywhere else in Switzerland. This brings out a well known factor, namely that climatic and environmental conditions have a great deal to do with the transmission of leprosy. A person with leprosy was discovered somewhere in the southern part of Germany. The German government did not know what to do with him. They put him in a freight car and shoved food and water within his reach. They then shunted this freight car from train to train and they got it across the Swiss border. Jadassohn was called to see this poor man whom he took to his hospital and even to his home and studied him intensively. Jadassohn thus established his concept of tubercloid leprosy and came to the conclusion that not only was the lepromin test positive in this tubercloid form of leprosy but also that it was impossible in this particular case to find the bacilli. These findings in leprosy were a further support of the Jadassohn-Lewandowsky law, which had been developed particularly in relation to tuberculosis, syphilis and fungous infections. This law states that wherever the immune mechanisms of the host are sufficiently active and adequate to produce a diminution of microorganisms or their virulence within the tissues of the host tubercloid structures may appear. In this law there is an explanation of a great many facts known in tuberculosis and, more important still, it clarifies the morphologic and immunobiologic relationships not only in regard to tuberculosis but also in many other chronic granulomatous infections such as leprosy, syphilis and certain fungous infections. There are many differences between these diseases but their fundamental relationship lies in the fact that the way in which the host reacts is due to his immunologic biologic status at the time his tissues encounter the products of microorganisms to the specific local status and general status. These specific immunobiologic states determine (1) the histology of the lesion (tubercloid structures or nontubercloid structures), (2) the number of bacilli present (rare or numerous), (3) the course of the disease (its prognosis, good or bad), (4) the contagiousness of the disease (which is to some measure, at least a corol-

try to the bacillary findings) and (5) the type of treatment and sometimes the response to the treatment. All these five follow immunobiologic laws which are now clearly discernible not only in leprosy and tuberculosis but in innumerable other infectious diseases as well.

DR ALFRED HOLLANDER, Springfield, Mass. I should like to ask Dr. Castello what experience he has had with the following method. During the time of my association with Unna in Hamburg we always tried to find bacilli with the solidified carbon dioxide method especially in nonspecific cases, when we could not find them by any other method. We put solidified carbon dioxide on the skin and produced a blister, and often when in these nonspecific cases we were unable to find any bacilli by other methods we found them by this method. Dr. Sulzberger mentioned the work of Jadassohn. I should like to call attention to the fact that Dr. Paul G. Unna has worked on leprosy since 1875. He has done some quite important work, especially on the histopathologic part of leprosy. He went to his friend Hansen in 1876 and after that he treated leprosy in his clinic in Hamburg. We always had between 10 and 20 patients, mostly from South America, isolated in our leprosy department.

DR PAUL GROSS, New York. It is a privilege to express admiration for Dr. Castello's presentation of the problems of leprosy and for his contributions to dermatology in general. One only need recall his paper on venereal lymphogranuloma published in 1926 to appreciate the tribute due to him and to the medical profession of South America in general. The distribution of the positive lepromin test among the various types of leprosy, as shown by Dr. Castello, seems to correspond in certain respects to the luetin test of syphilis. A positive luetin reaction seemed to depend on the development of the allergic state of tertiaryism with its pronounced tissue reaction and absence of spirochetes in the tertiary lesions. Similarly, the lepromin test is specific for the tuberculoid types of leprosy, which are distinguished by their tissue reaction and an absence or scarcity of lepra bacilli. It would be interesting to hear from Dr. Castello whether the lepromin test can be used to differentiate between sarcoid leprosy and sarcoidosis of tuberculous origin.

DR GUY H. FAGET, Carville, La. As yet in the United States we have not adopted this classification, but I can see that at the next International Conference on Leprosy it may possibly be adopted. I can see many valuable points in this new classification originated by the South American leprologists. As I understand it, we might consider the maculoanesthetic leprosy, or what the South American leprologists call the non-specific type of leprosy, as the transitional form, or the intermediate form between the more severe lepromatous type and the more benign tuberculoid type of leprosy. In the lepromin test, therefore, we have a significant and valuable prognostic test for the differentiating of the types of the disease. With this new world war and our American boys going into tropical countries there is a grave possibility of a large increase in leprosy in the United States. At the national leprosarium at Carville we are ready to take care of such additional cases, as we have the facilities there for the hospitalization of 480 patients and can make room for more if necessary.

DR FRED D. WEIDMAN, Philadelphia. A large part of the merit of the South American classification lies in what Dr. Castello indicated namely that thereby one can tie in certain of the newer features of leprosy with what we have always thought we knew about the morbid anatomy (the dermatology) of the condition. But morbid anatomy is not everything. It is in the nature of medicine at large to develop especially along bacteriologic, immunologic and public health lines and with such newer developments in leprosy the older classification has become more or less obsolete. At least it has been necessary to contrive some sort of an additional classification not necessarily a new classification, but an auxiliary classification whereby these 'basic science' aspects of leprosy may be reconciled and tied in with the morbid anatomy. Dr. Castello did not have time to elaborate on a certain sentence in the printed paper which I think he may care to dwell on in his closing

discussion, in which he speaks of the worthlessness of the lepromin test. That would seem to be contrary to what we have heard this morning. It would appear on the face of it that in the lepromin test as Dr. Gross stated, we have at once a valuable method for distinguishing tubercular leprosy from puzzling cases of sarcoid. This is the aspect of leprosy which gives me the greatest difficulty in differential diagnosis. I should like to have Dr. Castello say something too about the frequency of lazarine leprosy. I am sorry that he did not show a lantern slide of that condition. It does not look like leprosy at all. Certainly it is rare in the United States. I should like to have Dr. Castello tell us whether it is likewise rare in Cuba. When I read the paper there was one place where my mind stumbled and that was with respect to the use of the term 'follicular' as employed in connection with the histology. When one says 'follicular' to the general pathologist one thinks of such structures as the cortical follicles in the lymph nodes, and to the dermatologist the term follicular would conjure up thoughts of a hair follicle. The general pathologist prefers the term *miliary*. In tuberculosis we speak of *miliary* tubercles to indicate those which are sharply circumscribed. I take it, though that Dr. Castello's *follicular* is a literal translation from the Spanish and Portuguese but perhaps it will conduce to clarity in North America if we might substitute the term '*miliary*'.

DR V. PARDO-CASTELLO, Havana, Cuba. I want to thank you for this generous discussion. We have performed hundreds of lepromin tests on all types of patients and also on healthy men. We find in Cuba that all healthy men and women are lepromin positive. In other words, we live in a leprous country, we have been in contact with leprous persons for many years and we have developed immunity to leprosy, therefore our lepromin tests, my associates and mine are positive. We are trying to get hold of a number of Europeans who have not been in contact with leprosy and we are in contact with the immigration authorities in Cuba in order to perform lepromin tests on this type of men. Probably they will show negative, since they have not been in contact with leprosy. In reply to Dr. Hollander, we have tried, and so have all leprologists, to recover bacilli from the nonspecific types and the tuberculoid types by every method. Of course, some have been found but always in small quantities and in some cases it has been absolutely impossible to prove their existence. As far as sarcoid and tuberculosis are concerned I must recall to your minds that Dr. Balina of Buenos Aires and Dr. Rabello of Rio de Janeiro have reported cases of sarcoid caused by leprosy. Whether it is tuberculosis or a filtered virus we don't know, but sarcoid disease due to leprosy with the typical skin lesions clinically and pathologically and with lesions of the lymph nodes and lesions of the small bones of the extremities is indistinguishable from sarcoid of any other type. I do not believe that we can use the lepromin test to differentiate between these cases because as I said before, all Cubans are lepromin positive when they do not have leprosy of the lepromatous type, and therefore a case of sarcoid in Cuba or in any native of a country where the leprous abound would be lepromin positive. I want to emphasize that lepromin is not a diagnostic test. All attempts to make a diagnostic test with lepromin have been abandoned. It is a prognostic test and in that light is a very useful test. Dr. Weidman is right about the word *follicular*. In Spanish and in Portuguese we call *follicular* that type of tuberculosis which you call here '*miliary*'. It would perhaps be a good idea to change from '*follicular*' to *miliary*. I believe the lazarine type of leprosy is a special type of tuberculoid leprosy, that is these patients are lepromin positive and yet they have an enormous amount of bacilli in the necrotic part of the lesions, not in the tissues themselves. I interpret that as the Koch phenomenon in the case of leprosy the same as you would obtain in a case of tuberculosis with massive injection of tubercle bacilli when there already is a certain amount of immunity against tubercle bacilli. It is the massive infection somehow introduced into the system of the man who has high immunity and high defensive powers against leprosy and therefore the local lesions of the necrotic destructive type and the good prognosis with the positive lepromin test.

EVALUATION OF ANGIOCARDIOGRAPHY

HENRY K. TAYLOR, M.D.
Roentgenologist Coldwater Memorial Hospital
AND

TERESA McGOVERN, M.D.
Visiting Physician Columbia Medical Division Coldwater
Memorial Hospital
WEIFARE ISLAND, N. Y.

This report summarizes the examination of 100 persons by the Robb-Stemberg method.¹ The patient material comprises the groups included in the accompanying table. Many of the patients suffered from other ailments such as hemiplegia due to hypertensive cardiovascular disease, diabetes mellitus, nephritis and the like. However, this report is limited to the angiocardio-graphic study of the heart and major blood vessels.

TECHNIC

The angiocardio-graphic technic described by Robb and Stemberg was employed throughout the course of this study.

Patient Material for Evaluation of Angiocardiography

Type	Patients
Normal	18
Rheumatic heart disease	20
Arteriosclerotic heart disease	10
Hypertensive heart disease	20
Congenital anomalies	4
Aneurysms	11
Chronic intrapulmonary disease	10
Syphilitic heart disease	1
Pulmonary endarteritis	1
Leukemia	1
Tuberculosis	1
Total	100

Circulation time tests were determined by injection of solutions of ether, micasol,² dehydrocholic acid, sodium cyanide and saccharum. The results of these studies enabled us to calculate approximately the time at which the radiopaque substance would arrive at various locations.

A 70 per cent solution of diodrast (30 to 50 cc.) was injected intravenously and films were taken at predetermined intervals. Two such injections were found necessary for satisfactory visualization. In some patients three were required. Approximately fifteen minutes were allowed to elapse between injections. With each injection two exposures were made in the erect position at a distance of 6 feet. In several cases this entire procedure was repeated on one or two subsequent dates. For the average examination excluding the preliminary films four films were utilized: two in the posteroanterior position and two in an oblique position, thus obtaining roentgenograms of the right and the

left side of the heart in each position. In addition to these tests a few patients were examined in the supine position with the Bucky diaphragm at 36 inches.

All our observations are based on the technic described. At the present time we believe that this is sufficient for practical purposes. We believe, however, that much more information could be obtained through multiple serial exposures, as described by Sussman,³ and from motion pictures of the fluoroscopic screen.

REACTIONS TO DIODRAST INJECTIONS

Reactions to the injections of diodrast which at no time were alarming were as follows. Immediately after the injection each patient experienced a flushing of the head and neck, in addition to a profound sense of warmth throughout the entire body. Most of the patients salivated profusely, some became nauseated and others had coughing spells. All these symptoms, however, disappeared quickly. Eucis was noted only in those patients who had eaten prior to the injection. In some cases there was an urgency to urinate or to defecate, but in no instance did incontinence occur. A sense of weakness invariably accompanied or followed the procedure. Immediately after the injection the blood pressure dropped. In some cases the systolic drop was as much as 80 mm. of mercury and the diastolic drop from 50 to 60 mm. The hypotension, however, was of a transitory nature with a return to the preinjection level within five minutes and at the same time a disappearance of the sense of weakness.

Itching and urticarial rashes appeared in a few cases, increasing in intensity after the second injection. All were relieved by subcutaneous injection of epinephrine. None of the persons had been previously tested for sensitivity. Of all the patients examined 21 were subsequently given cutaneous tests for sensitivity. Sensitivity was determined by injecting intradermally 0.2 cc. of a 70 per cent diodrast solution into the volar surface of the arm. The wheal raised by this injection was measured and the area observed at ten minute intervals for an hour. Of this group 6 showed positive reactions within fifteen minutes; the others showed no reaction for more than one hour. A reaction was considered positive when the wheal, erythema and pseudopodiums measured more than 2.5 cm. in diameter. Some of these reactions appeared almost immediately, others did not appear for fifteen minutes.

The development of sensitivity to the contrast substance is a possibility and should not be overlooked.⁴ From the 21 patients tested there seems to be little or no correlation between the degree of sensitivity to an intradermal test with 0.2 cc. of 70 per cent diodrast and the reactions experienced at the time of the intravenous injection of 30 to 50 cc. of the 70 per cent diodrast. In 20 cases the injected vein became thrombosed within forty-eight hours but was subsequently recanalized.

ANATOMY—NORMAL HLARIS

Our examinations have shown variations from the recognized and accepted radiographic anatomy of the cardiac silhouette in the normal as well as in the abnor-

The Nopera Company supplied the micasol and the Winthrop Chemical Company the diodrast.

mal The present study indicates that existing concepts concerning the size, shape and position of the heart chambers and the thickness of its muscles are different from those observed in the adynamic viscus in the cadaver. Our concepts require modification in the light of observations made *in vivo* on the dynamic viscus.

Posteroanterior Position (fig 1A)—In this position, with contrast substance opacifying the superior vena cava, the right auricle, the right ventricle, the conus, the pulmonary aorta and the right and left pulmonary arteries, the entire right side of the heart appears to be a U shaped structure. The upper part of the right arm of the U is the superior vena cava and the lower part is the right auricle. When these two structures are combined they form the right border of the cardiac silhouette. In a number of instances we have observed a lack of filling with contrast substance in the right lower portion of the cardiac silhouette. This lack of filling when the right side of the heart is filled with contrast substance led to our excluding that portion as part of the right side of the heart. This region is therefore referred to as a silent area.

Pulsations with ventricular characteristics have been observed on kymographic examinations of this so-called silent area. Since we have also observed ventricular types of pulsations on that portion of the cardiac silhouette corresponding to the lower portion of the superior vena cava and the right auricle, we have concluded that the silent area is the site of the inferior vena cava and that the superior vena cava, the right auricle and the inferior vena cava are capable of transmitting ventricular pulsations.

The right ventricle is represented by the horizontal part and the lower portion of the left upright arm of the U. The left arm of the U is superimposed on the spine and seldom extends beyond the left lateral border thereof. The interventricular septum or the left lateral border of the opacified right side of the heart is vertical, with a tendency to convexity to the right. The apex of the right ventricle is usually represented as an acute angle far removed from the cardiac apex.

When the left pulmonary artery is outlined by contrast substance it is found to occupy only a small part of the left border of the cardiac silhouette, situated between the aortic knob and the superior portion of the left ventricle. The right ventricular conus does not participate in the formation of the left margin of the cardiac silhouette and only rarely does the pulmonary aorta reach that margin; instead these two structures are visualized deep within the cardiac shadow. The left pulmonary artery is below the thoracic aorta. At times, however, as the left pulmonary artery ascends, its left lateral border forms the lower part of the middle cardiac segment. The pulmonary aorta may be convex toward the left and it may extend to, but not beyond the left cardiac border.

The lateral dimension of the right side of the heart, in the posteroanterior position, as demonstrated with the aid of contrast substance is considerably smaller than our previous conception of it. When enlarged it does not approach the left border and is appreciably removed from the left lateral border of the cardiac silhouette.

When the left side of the heart is opacified the two chambers assume the shape of a figure 8 obliquely sit-

uated at about a 30 degree angle from the horizontal. The auricular shadow is circular in outline, forms no part of either border of the heart shadow and is disposed more to the right than to the left. In only 1 instance was the contrary observed. The ventricular shadow is more often seen to be oval, occupying the major portion of the left half of the heart, including the apex.

Further observations of the left cardiac border demonstrated that the middle segment (i.e. the area between the aortic knob and the base of the ventricle) might be composed of a part of the pulmonary aorta. The remainder of the border is a continuation of the pulmonary aorta at its bifurcation, as the left pulmonary artery. When the middle segment was not so composed we found it to be made up in whole or in part, by the descending portion of the left pulmonary artery or of the descending thoracic aorta as it descends and divides the cardiac silhouette.

In many instances there was a lack of filling with contrast substance of the lower portion of the middle cardiac segment, namely that portion above the base of the left ventricle. This is another so-called silent area as it

Fig 1—Normal heart. A posteroanterior view showing entire right side of the heart opacified. No contrast substance is present in the lower right portion of the cardiac silhouette (silent area). Apex of the right ventricle is seen considerably to the right of the cardiac apex. B heart pervade only half of the cardiac shadow.

lacks contrast substance when the left side of the heart otherwise is filled. In only 1 instance did this area fill with contrast substance. The outline obtained led us to believe that this area is occupied by the left auricular appendage.

These examinations also revealed variations in the position of the ascending and the descending aorta. They have appeared superimposed adjacent to and widely separated from each other. The ascending aorta rarely forms part of the border of the right side of the heart except when it is tortuous, elongated or dilated.

An aortic knob not demonstrable by routine examination can be demonstrated it present by angiocardio-graphy.

Right Anterior Oblique Position (fig 1B)—In this view, the position of the U shaped right heart is somewhat similar to that observed in the posteroanterior position. The only appreciable variation is a greater separation of the limbs of the U. The superior vena cava is visualized as it enters the right auricle. The right ventricle forms the horizontal and ascending portion of the U. In some cases a constriction in the contrast substance demarcates the site of the tricuspid ring.

The left pulmonary artery transversely crosses the clear space between the upper portion of the arms of the U. The opacified right ventricle does not occupy more than half of the ventral cardiac shadow in this position. Herebefore a larger portion of the silhouette was attributed to this structure. The left ventricular shadow on the

Fig 2—A left anterior oblique view showing the superior vena cava and the right auricle. B left anterior oblique view showing the right side of the heart as a rectangular structure with anterior convexity occupying ventral half of the cardiac silhouette.

other hand, occupies considerably more space than was previously believed.

The left auricle and left ventricle form a figure 8 lying in an almost horizontal plane, with the auricular chamber at a slightly higher level than the ventricular chamber.

In this oblique position the ascending and descending aortic shadows are not only parallel but also very close to each other, often being superimposed. There is no arch.

Left Anterior Oblique Position—The U appearance of the right heart as observed in the posteroanterior and right anterior oblique positions now changes into an elongated rectangular structure as the two vertical arms of the U become superimposed (fig 2). The right heart occupies the ventral portion of the entire silhouette.

Fig 3—A left lateral view showing the right side of the heart opacified. B left lateral view showing the left side of the heart and aorta opacified.

and is convex anteriorly. The chambers are superimposed and cannot be differentiated. The posterior limit of the contrast substance, representing the interventricular septum, is convex to the right.

In this position, the left heart forms a kidney shaped structure with a deep ventral concavity from the depths of which arises the aorta.

Lateral Position (fig 3)—In this position, the outline of the right and left portions of the heart shows little variation from the contours found in the left anterior oblique position of a normal heart.

VARIATIONS FROM THE NORMAL

The facilities at our disposal permitted the obtaining of only two films for each injection with contrast substance. Under the circumstances we endeavored to obtain as much information as possible, arranging our examinations so as to get as much as possible of the cardiovascular portion of each side of the heart opacified with each exposure. Because of technical limitation it was not possible in all instances to differentiate one heart chamber from another. However, separate opacifications of each side of the heart were obtainable. In the remainder of our presentation we shall refer to the right and the left sides of the heart as separate units, each unit being considered a combined auricular and ventricular shadow. Whenever possible we shall refer to the individual chambers.

Anatomic changes were apparent. There were variations in size and shape of the cavities and increased

Fig 4—A left anterior oblique view showing dilated right heart. B left anterior oblique view showing the left side of the heart with no demarcation between the left ventricle and aorta, indicating insufficiency of the aortic valve.

thickness of the cardiac muscle wall. These abnormalities could be readily differentiated from the variations normally occurring during systole and diastole.

Enlargement of the right heart chamber was manifested in the posteroanterior position by a generalized increase in the size of the U shaped structure with an advance of the interventricular septum to the left. The shift in the apical region was less pronounced than that in the area of the conus. In the left anterior oblique view the right side of the heart when enlarged assumed the shape of an inverted mushroom. In our opinion this signified enlargement of the chamber. The greatest enlargement was observed in the lower and posterior portion of the right side of the heart. The interventricular septum, in the region of the apex, was to a variable extent, convex to the left. This type of change was not necessarily accompanied by an increase in muscular thickness or by cardiac enlargement. It represented (or was interpreted as) simply chamber enlargement or dilatation without appreciable muscular hypertrophy or cardiac enlargement. Enlargement of the right side of the heart in some instances was present without the inverted mushroom appearance. In one type we observed the upper opacified area in the right side of the heart to be enlarged, whereas the lowermost,

or dependent, portion did not participate in the enlargement. The convexity of the interventricular septum occurred in either direction.

Enlargement of the left heart chamber could be visualized in all positions. The size and shape of the shadow determined whether the enlargement was auricular or ventricular and, if ventricular, whether the heart was in systole or diastole at the time of the exposure.

The left anterior oblique position yielded a characteristic roentgenogram. Whereas normally the left ventricle appeared as a small opacified sphere, when enlarged it manifested itself in one of two ways. In the first, the junction between the ventricle and the aorta was lost (fig 4B). This area was widened, the chamber was elongated and the entire configuration took on a tongue-like appearance, with the interventricular septum convex to the right. In the second, there was no loss of demarcation between the ventricle and the aorta. The chamber enlarged anteriorly, but the septal deviation remained convex to the right. The former enlargement is associated with an insufficiency or regurgitant lesion of the aortic valve, the latter with hypertension or obstructions at the aortic ring.

Fig 5—A left anterior oblique view showing the right side of the heart opacified cardiac hypertrophy. Clinically, hypertension cardiorenal disease. B same as A showing hypertrophy of the left side of the heart.

The diagnosis of mediastinal lesions was considerably facilitated by the use of contrast substance. It was possible to differentiate between mediastinal tumors and vascular lesions in the mediastinum, conditions which are not always easily diagnosed by kymographic studies. Transmitted pulsations on a kymographic record may be interpreted as vascular pulsations. We have observed kymographic studies of aneurysms with no evidence of pulsations and conversely, pulsations in mediastinal tumors. By angiocardigraphic studies we were able to differentiate mediastinal lesions from aneurysms with only 2 exceptions. In 1 case we were able to recognize multiple aneurysms arising from the arch of the aorta and also locate a large mediastinal mass in the retrocardiac area. This mass displaced the esophagus anteriorly and to the right and eroded the spine. Not being able to demonstrate any contrast substance within this mass, we were led to diagnose it as a neurogenic tumor in addition to the multiple aneurysms. At autopsy the mass proved to be a large aneurysm containing a huge laminated clot with a small lumen for the passage of blood. This postmortem examination made it quite clear why kymography had shown no pulsations and why contrast substance had not been allowed to accumulate in sufficient concentration to cast a recognizable

shadow. In another instance failure to demonstrate the aneurysm proved to be due to dilution of the contrast substance within a huge, diffuse dilatation occurring throughout the entire length of the descending aorta. Kymographic examination had revealed typical aortic pulsations synchronized with the aortic pulsations.

Fig 6—A posteroanterior view showing definite retraction of the mediastinal structures to the right secondary to pleural and pulmonary fibrosis of the right lung, compensatory emphysema of the left lung. Right side of the heart opacified plow shaped appearance. B posteroanterior view showing definite retraction of the mediastinal structures to the left secondary to pleural fibrosis and bronchiectasis and compensatory emphysema of the right lung. Note enormous U shaped right heart.

The distribution of the patients with aneurysms on the basis of etiology was as follows: cardiovascular syphilis 9, arteriosclerosis 2. Among the 9 patients with cardiovascular syphilis there were several with multiple aneurysms, including 1 in the abdominal aorta (fig 7). One of the arteriosclerotic aneurysms was a dissecting aneurysm and the other was saccular. Both were situated in the descending aorta.

Chronic pulmonary emphysema was characterized by right ventricular enlargement without generalized cardiac enlargement. In half of these cases we found the septum convex to the left corroborating the findings of Sussman and his co-workers.⁶ However in some cases

Fig 7—A slight obliquity with foreshortening of the left hemithorax showing multiple syphilitic aneurysms of the thoracic aorta. B same as A lateral view showing aneurysm of the abdominal aorta.

similar deviations were observed in which there was right sided chamber enlargement and no emphysema.

In 1 instance we found enlargement in the hilar regions, which we thought were due to multiple aortic

6 Sussman M L, Steinberg M F and Grishman Arthur. Contrast Visualization of the Heart and Great Vessels in Emphysema. *Am J Roentgenol* 47: 368-376 (March) 1942.

aneurysms (fig 10 *A*) Angiocardiography revealed large pulmonary arteries, the enlargements of which terminated quite abruptly

Obstructions to the large vessels leading to the right side of the heart were easily visualized as was the resulting secondary collateral circulation

Fig. 8—Arteriosclerotic aneurysm of the descending aorta of a white woman aged 95. *A* same as 4 posteroanterior view showing the entire right side of the heart opacified. *B* same as 4 posteroanterior view showing left side of the heart, aorta and aneurysm opacified.

In decided mediastinal deviations the size, shape and location of the heart and its chambers show significant variations from the normal. Intrinsic intrapulmonary obstructing factors existed which contributed to the changes observed. In 1 case in which the mediastinal structures were definitely deviated to the right (fig 6 *A*) secondary to a pleural and pulmonary fibrosis with bronchiectasis, the evidence of obstruction was quite profound. The pulmonary vessels were extremely dilated, a dilatation carried all the way back to the heart, the superior vena cava, the subclavian and the axillary veins. An extensive collateral circulation was also demonstrable. Angiocardiography showed enlargement of the right and left chambers. The interventricular septum presented an accentuated convexity to the right. In the posteroanterior position this septal convexity gave the right side of the heart a plow shaped appearance.

In a similar type case but with the decided deviation of the heart to the left (fig 6 *B*) the chambers assumed an entirely different shape. The right side of the heart was enlarged and the pulmonary vessels were extremely dilated. The U shaped structure appeared as a rectangle with the upright portions of the U dilated and widely separated.

One patient presented typical clinical manifestations of bronchiectasis which could not be verified by bronchography. He was studied in order to determine the morphologic appearance of the parenchymal pulmonary arteries, an obstructing lesion was suspected. Changes were observed which we interpreted as a pulmonary endarteritis, with an extensive intrapulmonary collateral circulation. The large vessels showed a sudden reduction in the size of the lumens.

There were 4 cases presenting congenital cardiovascular anomalies. In 1 we were able to establish the diagnosis by direct evidence. In 3 the diagnosis was confirmed by indirect evidence.

In a case of dextra aorta the position of the aorta was demonstrated beyond any doubt (fig 9).

In a case of coarctation definite on clinical evidence we were unable to demonstrate the constriction on three different occasions. On all examinations the arch and descending portion of the aorta down to the level of the sixth thoracic vertebra were visualized with contrast substance with no sharp demarcation between the upper and lower portions of the descending aorta. Examinations were made at ten, eleven, twelve, fourteen, fifteen and sixteen seconds following injections time factors which exceeded those determined by the circulation tests. Because of the consistency of the roentgen findings and despite the varying time factors we concluded that the area of coarctation was at the level of the sixth thoracic vertebra.

In another instance a diagnosis of patent ductus arteriosus had been made clinically in a 12 year old boy. The right side of the heart was visualized in two and one-half seconds and the left side of the heart in seven seconds. The left pulmonary artery formed a prominence in the middle cardiac segment and continued contrast substance during both examinations. Under normal circumstances the left pulmonary artery should have been free of contrast substance at the end of seven seconds and should not have been opacified along with the left side of the heart and aorta. The inference was that the contrast substance had arrived in the left pulmonary artery by way of the aorta.

In the fourth case a white man aged 35 had a clinical diagnosis of pulmonary stenosis. At the end of three seconds (fig 10 *B*) contrast substance was visualized simultaneously in the right and left ventricles, pulmonary aorta and pulmonary arteries. At the end of nine seconds contrast substance was present in the aorta and in the pulmonary arteries. The presence of contrast substance in both ventricles at three seconds could be accounted for only by an interventricular septal defect. Persistence of contrast substance in the large pulmonary vessels was further evidence of a septal defect.

The hypertensive type heart showed cardiac hypertrophy as was to be expected. In some instances the

Fig. 9—*A* posteroanterior view showing the left side of the heart and aorta opacified and aorta to the right of the spine. *B* left anterior oblique view. The left side of the heart is opacified showing loss of normal aortic curve resembling that observed in the right anterior oblique view.

hypertrophy reached enormous proportions, not only of the left ventricular wall but of the right as well. In others there was an accompanying enlargement of the left ventricular chamber (fig 5).

The arteriosclerotic hearts showed no true cardiac enlargement or hypertrophy but showed enlargement of

the right heart chamber⁸ More often, the inverted mushroom type of enlargement of the right side of the heart was found in these cases

As the right side of the heart enlarges, it appears, in the left anterior oblique position, as if the right ventricular apex were elevated and directed posteriorly, giving the impression that there might be a counter-clockwise or posterior rotation of the heart on a horizontal axis

The rheumatic hearts frequently showed evidence of cardiac enlargement This increase in size was due in some to enlargement of the chamber, in others to hypertrophy and in still others to a combination of the two conditions

Enlargement of the right side of the heart did not present the appearance of an inverted mushroom in the left anterior oblique position As the right side of the heart enlarges, the structures to the left of the base of the right ventricle may be displaced to the left and produce the convexity in the middle cardiac segment

At times the typical configuration ascribed to mitral hearts was noted Often there was an associated enlargement of the right heart chamber with little or no evidence of hypertrophy Some showed increase in the transverse diameter of the horizontal portion of the U between the right auricle and the right ventricle A loss of demarcation between the left ventricle and the aorta was attributed to valvular insufficiency

Those patients with clinical mitral stenosis showed large left auricles In the posteroanterior view the enlarged left auricle was disposed to the right and did not contribute to the formation of the left border of the cardiac silhouette However, when the left auricle is very large it forms part of the right border of the cardiac silhouette

We have been unable to demonstrate the left auricle on the left border, just as we have been unable to demonstrate the conus as forming the convexity of the middle cardiac segment We believe that as the left auricle enlarges and rotates posteriorly to appear on the right cardiac border structures lying to its left lateral border are pushed and form the convexity seen in mitral stenosis The structure called "conus" on the roentgenogram is not the anatomic conus The anatomic conus is an intracardiac and not contour forming structure We have found the convexity to be formed by the left pulmonary artery as it assumes an oblique intracardiac downward course instead of the usual horizontal

SUMMARY

1 A total of two hundred and fifteen injections were made with 70 per cent diodrast solution in a series of 100 persons, ranging in age from 12 to 93 years, in order to visualize the cardiac chambers and the large vessels Included in this group were persons with and without cardiovascular disease

⁸ By arteriosclerotic hearts we mean hearts in persons with no antecedent history of essential hypertension or myocardial infarction whose blood pressure does not exceed 130 in the systolic level or 90 in the diastolic who have definite evidence of peripheral sclerosis and who are 45 years of age or over They may have an anginal syndrome and/or electrocardiographic evidence of myocardial damage

2 Reactions to the injections were observed in most persons, but no reaction was severe enough to warrant discontinuing the examination and no patient objected to a second injection The chief reaction was a sharp transient drop in the blood pressure

3 This study yielded information of an anatomic nature of the heart and blood vessels, information at variance with the ordinarily accepted concept of the normal heart In contrast to our past concept concerning the anatomic positions of the cardiac chambers and the great vessels the following points were determined

A There is a deep location of the ventricular conus

B Pulmonary aorta as it arises from the ventricle is situated deep in the cardiac silhouette and does not form a prominence on the left border of the heart

C That portion of the cardiac silhouette above the base of the left ventricle and below the left pulmonary artery is usually not opacified with contrast substance and must indicate an area that is not hollow but solid

Fig 10—A posteroanterior view showing very large pulmonary arteries without any clinical evidence of parenchymal obstruction B, right anterior oblique view showing the superior vena cava, right and left ventricle and pulmonary arteries opacified in three seconds C posteroanterior view showing pulmonary endarteritis with extensive intrapulmonary collateral circulation

In our series, there was one exception and we thought it was the presence of a left auricular appendage

D The middle cardiac segment of the left border of the heart is formed by the pulmonary aorta and the left pulmonary artery

E The nonopacified portion of the lower right cardiac border is the inferior vena cava

F The right heart does not occupy the major portion of the cardiac silhouette in the posteroanterior projection The left ventricle occupies a considerable portion of the cardiac silhouette instead of, as previously supposed, only a small strip along the left cardiac silhouette

4 The following were demonstrated by angiocardiology

A Chamber enlargement

B Muscular hypertrophy

C Stenotic lesions

ABSTRACT OF DISCUSSION

DR M F STEINBERG, New York The development of contrast roentgenography of the cardiovascular system has stimulated the clinician and the roentgenologist to a clearer understanding of fundamental cardiovascular problems. Angiocardiography and arteriography have opened diagnostic vistas hitherto unattainable, and these may prove as rich as those resulting from the development of cholecystography, urography and encephalography. The application of this technic allows the most intimate study of circulatory anatomy and dynamics. The position of the pulmonic conus and the supravalvular portion of the aorta has been demonstrated within the cardiac shadow. The interventricular septum has been delineated and its position ascertained directly. A word of caution must be given concerning the value of measurements of the myocardial walls and the size of the chamber cavities. In serial exposures these have been found to vary greatly during systole and diastole. For the present it would be wiser to refrain from such measurements until one can be assured of synchronous exposures either in systole or in diastole. The value of angiocardiography in the differential diagnosis of mediastinal masses is indisputable. At the Mount Sinai Hospital all circumscribed mediastinal masses in the region of the vascular pedicle are studied preoperatively by this method in order to differentiate, as far as possible, the aneurysms. We have encountered 2 instances of proved aneurysm which were not operated. Hence, in the differential diagnosis of mediastinal masses, angiocardiography is most significant when the findings are positive. Drs Taylor and McGovern have confirmed our observations on the change in the position of the interventricular septum in cases of chronic lung disease. Convexity of the septum to the left occurred in 43 per cent of our series of 28 cases of emphysema, asthma, pulmonary fibrosis and bronchiectasis. However, in most of the cases which did not show this change we found some factor causing left ventricular strain, either hypertension or coronary artery disease. The most practical application of the value of angiocardiography in congenital heart disease has been found in confirmation of the clinical diagnosis of patent ductus arteriosus. Dilatation of the pulmonary artery or its branches is not pathognomonic nor is it a constant feature. We place great diagnostic importance, however, on the finding of a peculiar dilatation in the descending aorta just beyond the origin of the subclavian artery. This has been seen in no other condition than patent ductus arteriosus and was found in 26 of 27 cases. We believe that it represents either the infundibulum of the ductus or a traction aneurysm of the descending aorta due to the "pulling" effect of the short ductus.

DR MERRILL C SOSMAN, Boston I feel that we have gained considerable useful knowledge by the contrast cardiography, but this is still a highly specialized procedure and we must expect the men who are trained and equipped to do it to supply us with these new criteria so that we can interpret them or can use them in our interpretations of the films we get by ordinary means. I think probably the most valuable result of this work is the stimulation of a renewed interest in cardio-roentgenology.

DR HENRY K TAYLOR, New York The questions propounded by Dr Sosman are very pertinent. Unusual procedures are attempted only after all other methods have been tried, the deciding factor is always: How much will the patient benefit by them from either the diagnostic or the therapeutic standpoint?

The Heritage of Courage and Kindness—The most effective teacher is not the colorless intellectual virtuoso who today deals out as a fact what tomorrow may prove to be only a fancy, or who pursues some petty experimental project, but he is the real doctor who transmits to his pupils the heritage of truth, courage, and kindness that will make his spiritual heirs worthy members of the medical profession—Irving, Frederick C. THE FUNCTIONAL VALUE OF THE LIVER IN HEART DISEASE

AN EXPERIMENTAL STUDY

PROF DR IGNACIO CHAVEZ

DR B SEPULVEDA

AND

DR A ORTEGA I

MEXICO CITY

One of the organs that suffers most in heart failure is undoubtedly the liver. Its enlargement is the general rule in right congestive heart failure as well as in total ventricular failure. But if it is easy to appreciate the anatomic alterations—enlargement, tenderness, hardness and the like—the functional attack often passes unnoticed or at least is clinically underestimated. It is only in the advanced stages when subicterus, or rarely icterus, appears or when digestive disturbances become important that the physician directs his attention toward the liver and admits the existence of hepatic insufficiency. Nevertheless, at much earlier stages of congestion laboratory procedures already show the functional attack of the gland.

TABLE 1—Classification of Cardiac Patients

	With Decon- pensation	Without Decon- pensation
Rheumatic heart disease	19	3
Syphilitic aortitis	3	2
Arteriosclerotic heart disease	5	0
Miscellaneous group (congenital, cor pulmonale and pyrotoxic heart)	3	0
	<hr/> 0	<hr/> 0

It is conceivable that this hepatic involvement should be practically inevitable in heart failure, even in its early stages, as a result of a combination of factors: first, the engorgement of the organ with its consequent effects on the nutrition of the hepatic cell, second, general movement resulting from a defective pulmonary circulation, and, third, the possibility of an aggressive action of the cause of the heart disease itself—rheumatism, syphilis and like conditions.

In the face of scarcity of the usual clinical data, as well as the tardiness with which they appear, in view of the importance of a better knowledge of the functional capacity of the liver in our cardiac patients, and with the desire of learning whether or not the fourth factor mentioned, i. e. the aggressive action of the underlying cause of the heart disease, adds its part to the clinical picture of the congested liver, we have subjected a group of our cardiac patients to a certain number of experimental tests.

This particular chapter dealing with the functional exploration of the liver is one of the most debated in medicine. The literature on the subject is extensive without there being at present, complete agreement as to the value of the test proposed.

This lack of uniformity in criterion is explained by various reasons. 1 The liver has a multiplicity of

Because of lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Experimental Medicine and Therapeutics at the Ninety Third Annual Session of the American Medical Association Atlantic City, N. J. June 10, 1942.

functions some of which are so poorly understood that they cannot be correctly exploited. 2 Under pathologic conditions not all functions are affected at the same time or to the same degree—what has been called “functional asynergy” by Fiessinger and Walter. 3 The functional capacity of the organ varies constantly, the liver is a dynamic, not a static, gland, as Mann expresses it. 4 The liver has a great regenerative power and normally does not work at its full capacity. For the functional tests to give positive results an extensive attack of the gland carried to a more or less intensive degree is necessary.

These considerations of a physiologic nature, accurate as they are, do not invalidate the use of the tests, they only indicate certain conditions for their execution and fix certain limits as to the value of the results obtained. The following are the practical consequences that one may deduce from them: (a) It is necessary to perform several tests at the same time for the purpose of simultaneously exploring the greatest possible number of functions: it is the so-called “hepatic snapshot” of Fiessinger. (b) It is imperative to repeat the tests in order to obtain an idea of the evolution which the functions undergo in the course of time. (c) The results of the tests should always be confronted with clinical data.

Investigations that have filled these requirements and that have been carried out on cardiac patients are not very numerous as far as we have been able to determine. In 1930 Jolliffe¹ published a study on functional tests carried out on 16 patients with heart failure, in 1932 Robertson, Swalm and Konzelmann² reported the results obtained on 15 patients, most of whom were suffering from heart failure, in 1935 Routier, Cottet and Molinghen³ explored the livers of 35 cardiac patients by means of several simultaneous tests. Later on we shall compare the conclusions of these authors with our own.

CASES STUDIED

In the present research 35 patients with heart disease from various causes were studied, 30 of whom had heart failure and 5 had no insufficiency. Six of those with heart failure were examined for the second time after a disappearance of, or at least an improvement in, their insufficiency, which raises the number of observations to 41. Finally, 4 patients with liver disease were studied as a control group in order to check the results of the tests.

One group of cardiac patients was divided as shown in table 1.

For the convenient appreciation of the results, we have diagrammatically classified the heart failure of our patients into four degrees: 1, slight, 2, medium, 3, accentuated, 4, extreme.

The heart failure of all our patients was congestive. The enlargement of the liver was estimated according to the number of centimeters which it measured below the costal arch at the mammary line.

The patients were subjected to a careful clinical study as well as to roentgen examination, an electrocardiographic study, a previous urinalysis, chemical analysis of the blood, blood counts, a Boidet Wassermann test, determination of the sedimentation rate, and like laboratory examinations.

TESTS EMPLOYED

The tests conducted by us were:

- 1 Investigation of bile pigments in the serum: van den Bergh's reaction.
- 2 Measurement of urobilinogen in a specimen of urine.
- 3 Rosenthal's test with bromsulphalein.
- 4 The Takata-Ara reaction.
- 5 The induced galactosuria test.

BILIRUBINEMIA

For serum bilirubin determination we have followed Jendrassik's technic and have used Summerson's photoelectric colorimeter. We conducted first the ring test.

of Lepehne to determine qualitatively whether or not direct bilirubin was present, either immediate or delayed in its appearance. If it was negative we proceeded with the quantitative determination of indirect bilirubin, following the method of Jendrassik and Cziike. If it was positive and the ring of Lepehne revealed a weak reaction, we were satisfied with labeling it as such, without attempting the measurement, since the results obtained are always inexact if not misleading. In case of an intensively positive reaction, we proceeded to the separate determination of both bilirubins by the aforementioned method of Jendrassik and Cziike.

We accept as normal for indirect bilirubin 0.1 to 0.5 mg per hundred cubic centimeters of blood. This figure, determined by Barron⁴ using van den Bergh's reaction, is in accordance with our own experience.

1 Jolliffe Norman J Chin Investigation 8 419-433 (April) 1930
2 Robertson W E Swalm W A and Konzelmann F W Functional Capacity of the Liver Comparative Merits of the Most Popular Tests J A M A 99 2071-2077 (Dec 17) 1932
3 Routier D Cottet J and Molinghen P Arch d mal de l'app digestif 25 801 (Oct.) 1935

We have considered as abnormal the presence of bilirubin in the following conditions (a) when indirect bilirubin is greater than 0.5 mg per hundred cubic centimeters, (b) when direct bilirubin is present, whatever its amount, and (c), as is obvious, when total bilirubin is increased at the expense of its two fractions.

Of the 16 patients with heart failure studied by Jolliffe, 81 per cent showed an elevation of the blood bilirubin. On the other hand, in 14 cardiac patients, some with insufficiency and others without, studied by Robertson, Swalm and Konzelmann, not a single direct van den Bergh reaction was found, and as for the indirect they found it normal in the majority of cases, from which they concluded that this reaction is of little importance in the study of cardiac patients.

Inversely, Routier, Cottet and Molinghen³ affirm that in 31 patients with heart failure seen by them indirect bilirubin was always increased and the direct was positive in only 2 cases.

Our Results.—In the present study, which includes 33 tests carried out on 30 cardiac patients with varying degrees of heart failure (1 to 4), bilirubin was abnormal in 28, or 85 per cent. On the other hand, of 6 cardiac patients who had no decompensation, all had normal bilirubin. It is worthy of note that patient 12 bis had previously had during his course of heart failure a positive direct bilirubin reaction and a total bilirubin of 1.86 per cent. Another patient, 23 bis, with normal reactions, had also shown a few days before, during a grade 3 insufficiency, direct positive bilirubin and a total bilirubin of 1.50 per cent.

In table 2 it can be observed that

1 In the group of patients with heart failure, even if the failure was not constant there existed a close relation between the degree of failure and the amount of bilirubin, in the group with slight failures (type 1), in which there were 4, only 1 had a positive direct reaction and that was a patient with long-standing syphilis with aortitis. In the other 3, indirect bilirubin remained normal or hardly superseded the normal limit. In the group with failures of class 2, which included 13 patients, all presented direct bilirubin, and the total bilirubin, with the exception of 3 in whom it remained normal, reached figures which ranged between 0.5 and 1.7 mg, in the group with advanced failures (type 3), which included 11 patients all with 1 exception had direct bilirubin and total figures which reached 2.25 and 3 mg, finally in the group with grade 4 failures, which included 5 patients all had direct bilirubin and total figures were high from 1.36 to 6.9 mg per hundred cubic centimeters.

2 In this table it can be appreciated that there is no striking significant relationship between the cause of cardiac disease and the degree of bilirubinemia, still the impression is gained that it is in the group of patients with rheumatic heart disease that the highest figures of bilirubin are to be found.

3 Finally, it was not possible to appreciate a fixed stable relation between the degree of liver enlargement and the amount of bilirubin. Generally speaking the livers with the greatest amount of enlargement are those with the most pigment, but the exceptions are numerous as in case 33 bis, in which the liver measured 3 cm beyond the costal arch, and in case 16 in which the liver measured 8 cm and the bilirubin was normal while in others in which there was less enlargement of the liver very high figures were obtained.

BROMSULPHALLIN TEST

Since the studies of Rosenthal and White,¹¹ bromsulphalein has been the dye of choice used for studying elimination by the liver. The dose of 5 mg per kilogram of body weight which we used is the one recommended by O'Leary, Greene and Rowntree.¹²

There are cases in which the test is not applicable, as in frank jaundice, on the other hand if the amount of bilirubin is moderate the test retains all its usefulness. Snell and Magath¹³ after a survey of more than 10,000 tests of this kind performed in the Mayo Clinic, have concluded that bromsulphalein does permit one to judge the condition of the liver if bilirubin does not exceed 5 mg, and they even consider that it is perhaps the best functional test available at present.

In accordance with our experience we have considered as abnormal all retentions of the dye which are greater than 10 per cent thirty minutes after the injection. Retentions of this type were considered positive.

Jolliffe in the study already mentioned, using Rosenthal's original technique of an injection of 2 mg per kilogram of body weight found retentions ranging from 5 to 20 per cent in 75 per cent of his cases. Robertson, Swalm and Konzelmann with doses of 5 mg per kilogram, found in all of their 9 cases retentions greater than 6 per cent.

12 O'Leary, P. A., Greene, C. H. and Rowntree, J. G. Clinical Evaluation of Glucose Tolerance Test. Arch. Int. Med. **11** 155, 193 (Aug.) 1929.
13 Snell, A. M. and Magath, T. B. Use and Interpretation of Tests for Liver Function. J. A. M. A. **110** 167, 174 (Jan. 15) 1938.

Our Results—We carried out 38 tests on our 35 patients, 6 tests on patients without heart failure and 32 on patients with varying degrees of decompensation including various factors. Among those cases without failure the reactions in only 3 were negative, in the other 3 moderate retention rates, from 10 to 12 per cent, were present.

In the 32 cases presenting heart failure which are classified in table 3 we obtained the following results:

Five patients with heart failure grade 1 all gave a positive reaction, with retentions ranging between 12 and 30 per cent and averaging 21 per cent.

Ten patients with heart failure grade 2 all gave a positive reaction, with retentions ranging between 14 and 40 per cent and averaging 28.8 per cent.

Twelve patients with heart failure grade 3 all gave a positive reaction, with retentions ranging from 14 to 78 per cent and averaging 43 per cent.

Five patients with heart failure grade 4 all gave a positive reaction, with retentions ranging between 14 to 72 per cent and averaging 44.4 per cent.

It is of interest to note in table 3 that among those patients studied twice, once during heart failure and again after they had improved or been relieved of it, the retention of the dye decreased or disappeared, as in case 12, in which on the first test there was a retention of 28 per cent and after relief it went down to 10 per cent, and in cases 23, 22 and 32 presenting retentions of 48, 40 and 30 per cent respectively, in which on improvement the rates were lowered to 20, 30 and 12 per cent respectively.

THE TAKATA-ARA TEST

The Takata-Ara reaction, which when applied to the functional study of the liver should in all justice be termed the Takata-Jezler reaction, has been studied by numerous investigators but to date there is no uniformity of opinion with regard to its diagnostic or its prognostic value or even as to its technic, much less as to the explanation of its mechanism. Magath¹⁴ has recently made a revision of the subject, as has Naville in France.¹⁵ It is accepted that at present this reaction is entirely empirical and that it is most probable that it stands in relation with the absolute and relative amounts of albumin and globulin in the serum since its greatest occurrence is in connection with alterations of the blood proteins. Nevertheless it seems that the liver takes a direct part in the formation and regulation of these plasma proteins. The experiments of Jurgens appear to bear this out. This investigator has been able to modify the production of the serum proteins in the dog and goose by ligating the portal vein and by means of Eck's fistula. In these cases the reaction of Takata-Ara becomes positive but again becomes negative if the liver of the animal under experimentation is removed.

Fully aware that it lacks specificity and that there are extrahepatic factors which influence the proportion of serum proteins, such as feeding, conditions of the kidney, thyroid activity and the like we have included the Takata-Ara-Jezler reaction in the present study, more in the hope of gathering information on the subject than because of any idea on our part that it is a true test of hepatic function.

The results of the test have been different and even contradictory in the hands of diverse authors. Girard

and Vincent¹⁶ have found negative reactions in all their cases of cardiorenal disease complicated with heart failure. Crane¹⁷ obtained the same negative results in 3 cases of cardiac hypertension. On the other hand, Horejsi¹⁸ found a positive reaction of 37 per cent in 10 cardiac patients. Jezler, quoted by Wayburn and Cherry,¹⁹ reports 28 positive reactions among 218 patients with decompensation or a rate of 13 per cent. Wayburn and Cherry, studying 122 cases of that type of disease, found only 9 positive reactions, or 7.4 per cent, and in a survey of the literature they collected 453 case reports published by eight different investigators.

(themselves included). In this group there were 60 with a positive reaction or 13.3 per cent, a rate which might at present serve as a standard by which to judge the frequency of the reaction in the course of heart failure.

Our Results—In 30 cases of heart failure studied by us of different causes and of different degrees as specified in table 4, we found the Takata-Ara reaction positive in 19 or in 63.3 per cent. On the contrary, 7 cardiac patients without heart failure all had, with 1 exception, a negative reaction.

At a glance it can be appreciated that (1) the reaction is devoid of all specificity, for even though it is negative in all except 1 of the cases without heart failure it is also negative in all except 1 of the cases with slight heart failure and in several of those with

is a very much higher rate than the usual average of 13.3 per cent, does not fail to surprise us considerably. The only explanation that we can offer is that in the group of patients with advanced heart failure, subjected over long periods of time to dietary deficiencies, their hypoproteinemias is so advanced that it complicated a situation which is of itself highly chronic in undernourished persons with low protein intake, as frequently occurs among the poor people of our charity wards. Nevertheless it is well to note that we did not find any correlation whatever between the intensity of the Takata-Ara reaction and the degree of anemia or with the time of evolution of the disease or of the heart failure.

UROBILINOGEN

According to the technic proposed by Watson,²³ normal figures for urobilinogen in the twenty-four hours of the day vary between 0 and 4 mg., the most frequent being between 0.5 and 2 mg. a day. Notwithstanding that this procedure is extremely accurate we were not able to adopt it because of technical difficulties. It would

have been necessary to collect the urine of twenty-four hours, in addition to collecting the urine employed in the galactose test, also for twenty-four hours, all of which would have lengthened the process so much as to deprive it of its "snapshot" quality and at the same time would have postponed treatment of cardiac patients who were not in a condition to withstand a very long delay.

Consequently we selected Scott's technic, which also measures urobilinogen but requires only 1 specimen of freshly voided urine. It is true that the method can be criticized on the ground that urobilinogen is not uniformly eliminated in the twenty-four hours, but, since this varies within very short limits and Scott's method has the obvious advantages of simplicity and exactness, we adopted it as the method which seemed to suit our purposes exactly.

The normal amount of urobilinogen in fresh urine varies between 0.1 and 0.25 mg. per hundred cubic

This patient also showed renal insufficiency which account for the absence of galactose elimination.

centimeters, according to the figures given by Scott, but we call attention to the fact that in a considerable number of normal subjects it is not infrequent to find figures below the 0.1 mg. which we have just pointed out as a normal minimum.

Jolliffe¹ has found urobilinogen increased in more than half of his 16 cases (56 per cent). On the other hand, Robertson, Swalm and Konzelmann have found it normal in practically all their patients. Watson²² finds the rates elevated in 9 of the 11 patients studied by him (81 per cent).

Our Results—In our study we carried out the measurement of urobilinogen in 18 cardiac patients with heart failure and in 3 without it, as is shown in table 5, in which it can be seen that

1 In the small group of cardiac patients without heart failure not 1 had an increase in urobilinogen.

2 In the group of 18 patients with heart failure, only 5 maintained normal rates, and all were only moderately decompensated, the remaining 13, or 75 per cent, had high rates, but there was no significant correlation between these rates and the degree of failure.

3 Nevertheless, it could be observed that in 2 of them (cases 12 and 27), on improvement of their condition, the urobilinogen rates returned to normal.

4 Even though the number of observations is too small to permit us to generalize, it seems that in equal stages of failure the group of rheumatic patients presents higher urobilinogen rates than the other groups

5 There is no constant relation between the size of the liver and the degree of reaction

THE INDUCED GALACTOSURIA TEST

The original technic of Bauei consists in the oral administration of 40 Gm of galactose apart from meals and measurement of the amount of sugar in the urine five hours later. An elimination greater than 3 Gm is considered pathologic

cent in the first specimen and of 1 per cent in the second. In the third and fourth samples there should be no galactose at all

This was the method followed by us, and the details of its technic are set down in the beginning of this paper

Our Results—For the purposes of our study we began the test in 27 cases but were able to complete it in only 17. The other 10 were not taken into account because of the impossibility of obtaining one or more samples of urine at the required time. This fact was due to the presence of great oliguria, and we were

Fiessinger²⁵ and Thiebaut²⁶ consider that this method is not sufficiently sensitive and are of the opinion that better results are obtained if the fractional elimination is studied during the twenty-four hours rather than the total figure of galactose. In addition to the partial concentration of each specimen, these authors take into account the total concentration, according to the following formula

$$\frac{\text{total quantity of galactose in 24 hours} \times 1000}{\text{volume of urine in 24 hours}}$$

Finally they express the results of the partial concentrations in grams per thousand and consider as normal a galactose elimination of not greater than 5 per

therefore unable to correct it, even the catheter was useless in cases in which the urinary bladder was empty. This circumstance, and the great frequency with which it repeated itself—in one third of the cases—constitute a serious inconvenience in the use of the test for cardiac patients

The 17 completed cases, of which 15 showed decompensation and 2 did not, appear in table 8. It can be seen that 13 of the patients with heart failure had positive reactions and only 2 had normal reactions, 1 of them (27 bis) just as he showed improvement from his decompensation. A similar improvement reflected by the test was observed in 2 other patients who were cured of their heart failure, but these are not included in the table because study of these patients was not completed. Of the 2 compensated cardiac patients 1 had a positive and the other a negative reaction

25 Fiessinger N. Les explorations fonctionnelles. Paris: Masson & Cie 1935, p. 146.
26 Thiebaut F. Epreuves biologiques dans les ictères. Paris: Masson & Cie 1932.

In 10 of the cases studied we compared Bauer's and Thiebaut's methods, and in only 1 case were the results concordant. The other 9, positive according to Thiebaut's method, had normal elimination rates according to Bauer's technique. We have pointed out too many sources of error in both methods as regards the decompensated cardiac patient for us to place full confidence in one rather than in the other of the two procedures.

CENTRAL CONCLUSIONS

1 During heart failure the functions of the liver are profoundly disturbed. Blood bilirubin determinations and determinations of bromsulphalein and urobilinogen of the urine are positive as a rule, are perceptibly parallel to each other and usually keep a definite relationship with the degree of heart failure.

2 Tests which proved to be abnormal during heart failure turn back to normality when the latter disappears. When there is only an improvement of the circulatory condition, results follow in evolution which parallels such improvement.

3 In cases of heart failure functional hepatic disturbance does not usually keep a definite relationship with the cause of the heart condition itself. However, according to employed tests, the most accentuated hepatic disturbances are usually found in the group with rheumatic heart disease.

4 The Takata-Arai test is deprived of specific value and is of no use to evaluate the functional capacity of the liver.

5 The test of induced galactosuria is too influenced by circulatory disturbances, which renders it valueless as a hepatic test in heart failure.

Pasco de la Reforma 211

ABSTRACT OF DISCUSSION

DR. GEORGE HERRMANN, Galveston, Texas. This work reflects the ability of the clinicians of Mexico to recognize problems that we have neglected. Our free use of sugar and milk with its high calcium content and of xanthines in the presence of congestive failure might be a protection to the liver cells. Do our patients possibly have greater hepatic reserve? Somohinos Artois stated recently in Mexico that the blood uric acid level was an index as to whether the functional disturbance of the liver was going to progress and the patient die or whether it was going to regress. His slides showed a tremendous destruction of the liver such as we rarely see in our cardiac patients. We would be prone to attribute such liver necrosis to some other cause. In the light of Professor Chavez and Dr. Sepulveda's work we must more carefully study our patients with congested livers. Another point of interest was the preponderant number of patients with rheumatic heart disease in this series that showed liver disturbance. Rheumatic carditis, as Professor Chavez has described it, in Mexico is active much longer and is more severe than the rheumatic fever that we see in the Southwest. I should therefore like to know what percentage of these patients had tricuspid stenosis. An increased frequency of the tricuspid lesions might be one of the reasons why there is greater disturbance of the liver function in this series than we see in heart failure in the Southwest. The results of the galactose tests are surprising and indicate some disturbance in the important hepatic carbohydrate metabolism as well as the other functions. I don't believe that in Mexico they use sugar, milk and xanthines as freely in heart patients as we do. We have considered disturbances in the blood serum proteins as evidence of hepatic dysfunction and have found that a large number of our patients had lowered levels and disturbed plasma protein relationships. In some of these patients concentrated human blood plasma administered intravenously produced a diuresis and general improvement. Our cardiac patients suffer

from protein undernutrition probably less than the Mexicans do, and I would venture to predict that a large number of them would show a decrease in the blood serum proteins in the presence of such severe hepatic disturbances along with congestive failure.

DR. A. P. MUNSCH, St. Louis. It was a pleasure to listen to this extensive report on the experimental work done by Dr. Chavez and his collaborators. I am not aware that such a report exists and more than one thing has happened as a result of it. It gives us a standard to go by in comparison and it calls attention to an important condition. I believe that nearly all cardiologists and medical men have remained in the background in considering the importance of liver function clinically in cardiac failure. We are all aware of the importance of the liver function. We are aware that in cardiac failure there is a pathologic congestion to a greater extent. We are also aware that my organ that is congested cannot function normally. Therefore the normal function of the liver is impaired. Dr. Chavez has shown us through his commendable results from experimentation, a great deal about this damage. The realization of the points brought out by him will enable us to help at least to take the load off the damaged liver and in so doing lessen the embarrassment of the heart as well as that of the patient. He has given us an important thought and message to remember—that in cardiac failure it is important to consider the damaged liver function. It undoubtedly accounts for more deaths than we realize. As a result of his calling the attention of this audience to this subject all of us will go away with a greater realization of its importance and with a happy memory of the doctor who came to us from Mexico City to wake us up on this matter.

DR. IGNACIO CHAVEZ, Mexico City. Dr. Herrmann has reason when he says that there may be more hepatic reserve here among patients in the United States than in Mexico. Our pathologists are accustomed to seeing lesions in the liver at autopsy which are more severe than those seen in the hospitals of other parts of the world. It seems as if the livers of our people are much more damaged. I don't know whether it is due to deficiencies in the diet, alcohol or some other factor but that is the fact. In heart failure we are accustomed to seeing the liver show not only greater congestion but greater destruction—necrosis and cirrhosis—than is normally seen in other countries. Dr. Herrmann also says that he is surprised at the great number of patients with rheumatic disease in comparison with the other forms of cardiopathy. That is true also. Among our poor rheumatism is so widespread that it is the greatest cause of heart disease in Mexico. In Cleveland at the meeting of the American Heart Association I pointed out that in Mexico City in the high altitude of our high plateau is where the highest figure of rheumatic heart disease has ever been shown. In my own statistics of 2,400 organic cardiac cases I have shown that 61 per cent of them in the charity hospitals are of rheumatic origin. It is 50 per cent more than in Boston, Washington, Paris or London. In no part of the world has there been shown so great an incidence of rheumatism in heart disease. As to the comments of Dr. Munsch I can only say that we think that the liver in the cardiac patients passes through two periods. In the first period when the heart failure begins, the liver trouble is reversible. It is only a functional attack. In the second period when the lesion has been established, the tests are more and more abnormal while the heart condition is more advanced. The lesions are tremendous and they are of irreversible nature. That is the reason why sometimes, when the heart condition improves the tests remain abnormal. A certain injury to the hepatic tissue remains. We do not employ any particular treatment for this liver condition while the heart failure is not anchored. We treat these patients as heart patients, and the only point that we have always in mind is not to give them digitalis by mouth when the liver is greatly congested. Our routine procedure is to give them digitalis by intramuscular or intravenous injection. When the heart failure disappears and the liver insufficiency persists, then it is necessary to use a certain treatment for this condition depending on the grade and the type.

Clinical Notes, Suggestions and New Instruments

A HIGH PROTEIN BEVERAGE

LOUIS BAUMAN, M.D.
WITH THE TECHNICAL ASSISTANCE OF
MISS HERMALINE GAGE B.S. NEW YORK

Low serum proteins are encountered in a number of conditions including diseases of the liver, kidney, stomach and intestine and during protracted convalescence from operations on the alimentary canal, e.g. after abdominal perineal resections of the rectum and in extensive and prolonged infections of burns. The ingestion of solid food by many of these patients is inadvisable or unacceptable, and the intravenous injection of proteins or amino acids over a prolonged period may not be entirely practicable or economical.

Therefore it seemed desirable to prepare a beverage that is rich in biologically important proteins. For this purpose we used a base of milk or evaporated milk to which egg white and powdered milk (Dryco) was added.

TABLE 1—Composition of the High Protein Mixture per Thousand Cubic Centimeters

Ingredient	Grams	Carbohydrate, Gm	Protein Gm	Fat Gm	Calcium Gm	Phosphorus C'm	Iron Mls	Vitamin A Inter national Units	Thiamine Mg	Vitamin C	Riboflavin Mls	Vitamin D Inter national Units
Milk	675	31	21	25	0.73	0.58	1.3	1,000	0.50	—	1.58	3.30
Dryco	150	69	48	18	1.50	1.12	—	3,150	0.24	—	—	495
Egg white	800	2	52	—	0.04	0.05	0.3	—	—	—	0.68	—
Total, 1,100 calories		102	101	43	2.27	1.85	1.6	4,150	0.84	—	2.26	300+
1 glass 200 cc 240 calories		20	20	0	0.45	0.37	0.3	830	0.17	—	0.41	100
Measures of food used												
Milk									2½ cups			
Egg white (frozen)									1½ cups			
Dryco									1½ cups			

TABLE 2—Recommended Daily Allowances for Specific Nutrients

Food and Nutrition Board of the National Research Council

	Calories	Protein Gm	Cal Gm	Iron Mls	Vita min A I U	Thia mine Mg	Ribo flavin Mls	Nico tinic Mg	As corbic Acid Mg
Man (70 kg.) moderately active	3,000	70	0.8	12	5,000	1.8	2.7	18	75
Woman (55 kg.) moderately active	2,500	60	0.8	12	5,000	1.5	2.2	15	70

The method of preparation is simple. It consists in mixing milk powder gradually with frozen egg white which has been beaten until foamy (but not dry) with an egg beater and then adding the milk while the mixing process is continued. Filtration through one thickness of gauze will remove the egg membrane.

Such a mixture can easily be prepared in a field hospital from canned or dry material and can be fortified with vitamin concentrates or cream if added calories are required. The day's supply is prepared in the morning and kept cool in the refrigerator. When served, each glass may be sweetened with sugar and flavored with vanilla chocolate, coffee, malt extract or molasses.

It is also a practical mixture in the medical treatment of duodenal ulcer. Most patients consume this mixture with relish, though occasionally a distaste for milk is encountered and considerable urging may be necessary.

In table 1 the composition of the mixture is given in detail. Table 2 shows the daily allowance for specific nutrients recommended by the Food and Nutrition Board of the National Research Council.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

WESTERN ELECTRIC ORTHO-TRONIC AUDIPHONE ACCEPTABLE

Manufacturer: Western Electric Company, 300 Central Avenue, Kearny, N. J.

The Western Electric Ortho Tronic Audiphone is a vacuum tube hearing aid with microphone and amplifier housed in molded plastic case. A and B batteries are contained in separate leather case. The weights and overall dimensions of various parts are as follows: 125 A 3 amplifier, 5¼ inches by 2¼ inches by ¾ inch weight 575 ounces.

Battery case, 5¼ inches by 2½ inches by 1 inch weight 128 ounces.

714-A } Air receiver without molded earpiece 7¼ inch by ½ inch
714-B } diameter weight 0.31 ounce
714-C }
715-A—Bone conduction receiver 1½ inches by ¾ inch by 1 inch weight 0.81 ounce

Batteries: The current supply is A battery, 1.5 volt, size D drawing 90 milliamperes at full volume. B battery, 45 volt No. 455, drawing 10 to 22 milliamperes under operating conditions.

Acoustical Gain: The microphone amplifier unit carries three controls, an on and off switch, volume control and tone discriminator, operated by knurled disks at the top of the instrument. The volume control serves the usual purpose of regulating the degree of amplification, and the tone discriminator changes the degree of amplification as between the high and low frequencies. Curves submitted show that the shift from "full tone" to "minimum tone position" suppresses frequencies below 1,000 cycles much more than frequencies above this value. Tests verify this claim, as shown later.

Western Electric Ortho-TRONIC Audiphone

The following amplifications for intensity slightly above normal ear threshold give the order of magnitude of the increase of sound intensity levels at the ear of the wearer over that at the microphone under normal use.

They do not give the maximum possible gain under ideal conditions nor the electrical amplifications as shown by measurements of electrical input and output.

		Frequency				
Receiver	Tone Setting	128	256	512	3,000	4,096
714 A	Minimum	Nil	2	15.35	14	13
714 A	Maximum	Nil	26	50.48	17	13
714 B	Minimum	Nil	15	25.44	19	13
714 B	Maximum	Nil	19	56.46	23	13
714 C	Minimum	Nil	2	22.34	16.5	16.5
714 C	Maximum	Nil	15	29.42	15.0	15.0

Acoustical Feedback: The foregoing values were shown with volume setting approximately two-thirds full on. As usually occurs in instruments showing high gain the maximum gain attainable in use is determined by the closeness of the fit of the earpiece in the ear. Tests made using a custom fitted earpiece showed that a volume setting of five-sixths of full volume was the maximum with receiver 714 A, tone control setting at maximum and two-thirds full volume with tone control setting at minimum. With receiver 714 B five-sixths of full volume could be obtained without feedback for both maximum and minimum settings of tone control. Practically full volume could be obtained with 714 C receiver for both tone control settings.

Articulation: The usual syllable and sentence lists were used with a hard of hearing subject at a distance of 5 feet in a quiet room with instrument set for comfortable hearing and using each of the three air conduction receivers and the bone receiver. These tests showed satisfactory performance for all combinations. The instrument is well made.

The Council voted to accept the Western Electric Ortho Tronic Audiphone for inclusion in its list of accepted devices.

SATURDAY, APRIL 17, 1943

B₁ VITAMIN HYPOIMMUNITY

As part of a long range program of study of the relation of diet to virus infections, Foster and her co-workers¹ of the University of Pennsylvania studied the relative susceptibility to poliomyelitis of mice maintained at different levels of vitamin B₁ (thiamine) intake. At the luxury level mice were given diets containing 100 micrograms of thiamine per hundred grams of food, which more than covered their full nutritional requirements (thiamine excretion not determined). Other groups of mice were maintained on a diet containing as little as 10 micrograms of thiamine per hundred grams. This usually led to signs of deficiency within fifteen days, with death of 40 per cent of the mice within thirty days. Still other groups were given thiamine at the minimum maintenance level, after partial depletion at the 10 microgram level, their thiamine intake being increased to 30 micrograms per hundred grams. The majority of these animals remained healthy and at stationary body weight for at least thirty days. After from fifteen to thirty-four days on these differential diets each animal was inoculated intracerebrally with 0.03 cc of a 0.5 per cent suspension of poliomyelitis infected mouse brain, control inoculation being made with uninfected brains.

In a typical experiment 36 mice were maintained for thirty-four days at the luxury thiamine level. On inoculation with the routine test dose 30 mice (83 per cent) developed typical paralysis, from which all died within thirty days, 3 additional mice (8 per cent) of the group dying without showing paralytic symptoms. A parallel group of 24 mice were maintained at the deficiency (10 microgram) thiamine level. On inoculation but 4 mice of this group (16 per cent) developed lethal paralysis, while 6 mice (25 per cent) died without showing paralytic symptoms, control tests suggesting that these additional deaths were due to thiamine deficiency.

In this experiment the incidence of lethal paralysis was increased fivefold as a result of the luxury vitamin B₁ intake (or decreased fivefold as a result of thiamine deficiency). Even more striking results were obtained in a second experiment, in which comparison was made with mice maintained at the 30 microgram level. Here there was a sevenfold increase in the number of lethal paralyzes at the luxury vitamin B₁ level, when compared with the number at the minimum (30 microgram) maintenance level. If one should take the average of all groups, their data suggest a sixfold increase in poliomyelitis susceptibility as a result of a slight excess of vitamin B₁ (or a sixfold increase in resistance as a result of vitamin B₁ subnutrition). Thus viewed, urinary excretion of excess thiamine² becomes a purposeful defensive mechanism to prevent thiaminogenic viral hypimmunity.

Thus far the Pennsylvania pediatricians have avoided offering a theoretical explanation of this wholly unexpected phenomenon. In their opinion the length of survival of the virus and the nature of the histologic lesion in thiamine deficient mice must be determined before a definite theory can be formulated. It would be in line with the present tendency in immunologic research, however, to assume that thiamine is a necessary nutritional factor for the symbiotic multiplication of the polio virus, a relative abundance of thiamine leading to its increased proliferation, with thiamine subnutrition inhibiting proliferation. Such a theory would be essentially a renaissance of the original Pasteur exhaustion theory of acquired immunity, a discarded theory now being reconsidered by numerous investigators, particularly in its application to the phenomenon of virus antagonism.³

For some time a somewhat similar phenomenon has been under investigation by plant pathologists. Growers of narcissus bulbs, for example, have attempted to obtain superior flowers, increased bulb production and increased disease resistance by the use of numerous artificial plant hormones or synthetic growth stimulants. Stuart and McClellan⁴ of the U. S. Department of Agriculture tested such possibilities. To their disappointment they found that, far from protecting bulbs from disease, such growth hormones stimulated the growth and apparently increased the pathogenicity of basal rot fungus (*Fusarium oxysporum* f. *narcissi*) and thus increased commercial loss from basal rot.

That thiamine has a somewhat similar stimulating effect on the poliomyelitis virus is the essential tentative suggestion from the results that have been reported by the Pennsylvania pediatricians. Whether or not vita-

mm B₁ possesses a similar synergistic action with other vitamins, when it is tested in other animal species or by other methods of injection, however, has not yet been determined

The difference between the sevenfold and fivefold ratios drawn from Foster's data suggests the tentative conclusion that the maximum natural resistance to poliomyelitis virus is obtained from a minimum full maintenance level of vitamin B₁ intake and that intakes either above or below this level cause decreased resistance. If this should be confirmed by future tests, it would form a new rational basis for dietary hygiene and clinical therapy

SUNLIGHT CARCINOMA AND OTHER TUMORS INDUCED BY ULTRA- VIOLET RADIATION

Tumors of the skin of exposed parts of the human body in most cases are epidermal carcinoma, mostly of the squamous variety. Clinical observations and statistical study support the view that the most important cause of this carcinoma is sunlight, specifically the ultraviolet rays of the spectrum. For instance, more carcinoma of the exposed skin of white men occurs in the southern than in the other parts of this country. Farmers, sailors and other outdoor workers are more frequently victims of such carcinoma than persons less exposed to sunlight. Experiments have shown, moreover, that cancer of the skin as well as of other tissues is easily induced in albino mice and other animals by ultraviolet radiation under well controlled conditions. It has been found by Blum and his co-workers¹ at the National Cancer Institute that in mice ultraviolet radiation penetrates the skin to some depth and thus can act on a variety of cells, inducing different kinds of tumors.

The most recent analysis of the results of extensive experiments by Blum and his associates² showed that spindle cell sarcoma predominated while squamous carcinoma formed a smaller group often combined with sarcoma. Also hemangioendothelioma, osteochondrosarcoma, sebaceous carcinoma and even tumors of the eye developed in mice exposed to ultraviolet radiation, indicating that ultraviolet rays can induce tumors in various tissues depending on their susceptibility to its action and limited by the penetration of the rays. It would seem, then, that ultraviolet radiation can induce tumors in any susceptible tissue it may reach.

Why do not other forms of tumor besides epidermal carcinoma develop frequently in men freely exposed to sunlight? The reason appears to be that in man the amount of radiation reaching the dermis at best is not

sufficient to induce the growth of tumors—sarcoma, and so on—of cellular elements in the dermal tissue. The workers at the National Cancer Institute found that the transmissibility of carcinogenic wavelengths by the human epidermis is much lower than by the mouse epidermis. In fact, in well tanned human skin almost no rays could reach the dermis. That white persons, especially blonds, seem more susceptible than Negroes to carcinoma of the exposed skin suggests that the pigment in the epidermis protects against the carcinogenic effect of ultraviolet rays.

VITAMIN E DEFICIENCY

Evans and Bishop¹ in 1923 concluded that certain natural foods, notably wheat germ and many plant leaves, contain a factor essential for normal reproduction in the rat. This substance, later called vitamin E, was shown to be essential for the successful completion of intrauterine growth as well as for the maintenance of testicular function in the male. The female mouse, like the rat, shows typical resorption of the fetuses when restricted to vitamin E deficient rations, whereas in the male mouse degenerative changes in the germinal tissues of the testes have not been demonstrated.² Again eggs from hens on a diet poor in vitamin E show early embryonic mortality and low hatchability. Vitamin E has been isolated, characterized chemically and synthesized, while the name alpha tocopherol has been given to an alcohol obtained from wheat germ oil, several other compounds possess similar biologic activity. Other functions have been demonstrated for the tocopherols during the past decade, but the part they play in promoting successful reproduction seems to have characterized these compounds from the functional point of view.

The striking gross feature of the reproductive failure in the female white rat restricted to diet deficient in vitamin E is the death and resorption of the fetuses when about two thirds of the gestation time has elapsed. In subsequent matings the same phenomena are seen unless vitamin E is administered, when normal reproduction again ensues. Adamstone³ observed that in eggs from hens on feed poor in vitamin E the chick fails to hatch because of the development of a so-called lethal ring in the blastoderm, formed from cell proliferation in the mesoderm. This obstructs the blood vessels of the blastoderm and they disintegrate, the embryo dies from hemorrhage, ischemia and starvation. The mechanism of embryonic death in the mammal on diets deficient in tocopherol has recently been elucidated by Mason.⁴ In a large number of observations on 16 day old rat embryos he observed widespread hemorrhages on the surface in the head, shoulder and trunk

regions in plexiform patterns. The lesions were characterized by vasodilatation, congestion and vascular stasis of the superficial blood channels with subsequent bleeding into the various parts of the central nervous system. The general conclusion is reached that there develops in this specific nutritional deficiency a structural weakness of the vascular system leading to stasis and that death is due to the consequent progressive ischemia of the fetal tissues.

Elucidation of the biochemical defect induced by a deficiency in vitamin E is significant not only on its own account but also because it helps to temper the conception of functional specificity of the vitamins. Particularly important is recognition of the extent to which the tissues of the body are sensitive to slight chemical changes in the blood and lymph on which their metabolism depends.

Current Comment

RENAL VASCULAR DISEASE AND HYPERTENSION

The demonstration by Goldblatt¹ that chronic hypertension regularly follows partial clamping of the renal arteries of dogs and by Moritz and Oldt² that people with chronic hypertension usually show diffuse renal arteriolar sclerosis at necropsy, whereas normal persons rarely have such sclerosis, suggests that renal vascular disease in man may be the etiologic counterpart of the Goldblatt clamps in the dog. Although it has been recognized that degenerative vascular disease often follows the appearance of hypertension, the new evidence lends support to the view that renal vascular disease may often be primary and causal. A recent study of renal biopsies from 100 human subjects incident to the performance of splanchnic resections for hypertension afforded Castleman and Smithwick a unique opportunity to investigate an earlier stage of the disease than had been theretofore studied. Although all their patients had severe chronic hypertension, the renal vascular disease observed in 53 was so slight that it seemed unlikely in the opinion of the authors "that the blood flow could have been embarrassed sufficiently to be the one factor responsible for the hypertension." Thus it would appear that most if not all of the degenerative arteriolar lesions observed in persons dead of the effects of chronic hypertension should probably be regarded as secondary rather than primary. The observations of Castleman and Smithwick³ provide some degree of morphologic confirmation of the conclusions of Homer Smith⁴ and his associates, who found from renal blood flow studies that "there exists a perturbation of vascular function which is primary in time and causality to the destruction

of renal parenchyma." Whether the renal arteriolar lesions represent the late structural manifestation of a primary "perturbation of vascular function" or the mechanical effects of a prolonged elevation of intravascular pressure is not yet clear.

BOTULISM

Meyer and his associates in California have gathered statistics on 367 outbreaks of botulism in the United States since 1899. Only 83 of the outbreaks have been due to commercially canned foodstuffs, with one possible exception, outbreaks have not occurred in nearly twenty years from this source. The other 284 outbreaks have been caused by foods canned in the home. The total cases of the disease for the forty-three years numbered 1052 with 687 deaths, a fatality rate of 65 per cent. How many other unrecognized cases have occurred is unknown. During the coming canning season many persons who never before attempted home canning will preserve garden produce. The danger from botulism is ever present unless proper precautions are taken. Faust's⁵ disensuing methods of home canning, emphasizes the necessity of the pressure cooker with an accurate gage or thermometer for nonacid foods such as string beans and corn. Any such foods that have been processed in any other manner must be reboiled for at least fifteen minutes before tasting or using. Any home canned food that shows the slightest evidence of spoilage should not even be tasted for the toxin of the *botulinus* bacillus is the most powerful poison known. The problem calls for concerted effort by agricultural advisers and public health personnel in warning against faulty methods of home canning and alertness of physicians in recognizing symptoms and administering antitoxin early and in adequate amounts.

MARMOLA IS DANGEROUS TO HEALTH

Any drug which may expose the users to disease and pain when taken in the dosage and with the frequency recommended and suggested in its labeling is dangerous to health. Marmola is such a drug. Held the U. S. District Court for the Western District of Wisconsin in a recent case.¹ This proceeding was predicated on the contention that the article was dangerous to health when used in the dosage or with the frequency prescribed, recommended or suggested in its labeling and on the further ground that the labeling was false and misleading because it failed to reveal facts material with respect to the consequences which might result from the use of the article under the conditions of use prescribed thereon. In sustaining the government's contentions, the court pointed out that a substantial portion of the public, after reading the labeling used in connection with the product, would conclude that obesity is caused by the lack of some substance in the human body that Marmola supplies and that Marmola is a safe and efficient remedy for obesity, which is not a fact.

⁵ Faust, Hilda. Nutrition Program During the War—Home Canning. University of California College of Agriculture, Berkeley.

¹ U. S. v. 62 Packages More or Less of Marmola Prescription Tablets, decided Feb. 23, 1943 by the District Court of the United States for the Western District of Wisconsin (No. 109 Admiralty).

The administration of thyroid in the dosage contained in Marmola, the court thought, constitutes a dangerous procedure which should not be undertaken without a thorough examination of the prospective user by a competent physician and then only under the supervision of the physician. While the federal act was not intended to prevent self medication, the court observed, it was enacted to make self medication safer and more effective. An imposing list of expert witnesses testified in this case for the government and for the intervenor, the Raladam Company. The decision of the court lists these witnesses without in most instances indicating the exact nature of the testimony they offered. Among those testifying for the Raladam Company were

Dr Abbott W Allen, New York, assistant clinical professor of medicine of Columbia University, Dr John A Killian, Englewood, N J, professor of biochemistry at the New York Post-Graduate School of Columbia University, Dr Phinn T Morse, Detroit, consulting pathologist, Dr William A Spitzley, general practitioner, Dr Benjamin H Schlomovitz, Milwaukee, professor of pharmacology and toxicology, Marquette University Medical School, and Dr Andrew I Rosenberger, Milwaukee, a specialist in diseases of the nervous system.

Among the witnesses who offered testimony in support of the government's contentions that the distribution of Marmola in interstate commerce was unlawful were

Dr James Short, New York, and Dr Frank Stites, Louisville, Ky, both specialists in internal medicine. Dr Elmer L Sevringhaus, Madison, Wis, professor in the Medical School of the University of Wisconsin and a specialist in metabolic and endocrine diseases, Dr Willard O Thompson, Chicago, professor in the Medical School of the University of Chicago and a specialist in endocrinology and metabolism, Dr Louis H Newburgh, Ann Arbor, Mich, professor in the Medical School of Michigan University and a specialist in endocrinology and metabolic diseases, Dr Israel Bran, Philadelphia, a specialist in thyroid diseases, Dr Russell M Wilder, Mayo Clinic, an instructor in the Medical School of the University of Minnesota and a specialist in the treatment of diabetes, Dr Samuel F Hames, Mayo Clinic, head of the section of the clinic pertaining to thyroid diseases and associate professor at the University of Minnesota, Dr William Oatway, Madison, Wis, a member of the faculty of the Medical School of the University of Wisconsin, Dr Chester M Kurtz, Milwaukee, a member of the faculty of the Medical School of the University of Wisconsin and a specialist in heart diseases, Dr Anton J Carlson, Chicago, who formerly held a professorship in the Department of Physiology at Rush Medical College and the University of Chicago from 1904 until recently, when he retired, and Dr Marian S Kimble, Madison, Wis, a chemist who, as an investigator, made tests as to the value of desiccated thyroid as a remedy for obesity.

One of the concluding paragraphs in the court's opinion merits a direct quotation:

The Court is thoroughly convinced, by a preponderance of the evidence, that Marmola when used as prescribed in the labeling thereof, is neither a safe, appropriate nor an efficient remedy for obesity, that it is dangerous to the health of the user when used in the dosage or with the frequency and duration prescribed, recommended or suggested in the labeling thereof, that the packages of Marmola in question, when seized in these proceedings, were misbranded within the meaning of the sections of the Federal Food, Drug and Cosmetic Act involved herein that the labeling on Marmola is false and misleading in its representations that it is a safe remedy for obesity, and in that it fails to reveal facts material with respect to consequences

which may result from the use of Marmola under the conditions prescribed in the labeling.

Thus unfolds another chapter in the existence of a preparation the dangers of which have been repeatedly pointed out in *THE JOURNAL* and which has received the attention of the federal government for over a decade. If this is not the final chapter, how long will it go on?

SWINE LUNGWORM AS RESERVOIR FOR SWINE INFLUENZA VIRUS

Shope's work on the swine lungworm as a reservoir and intermediate host for the virus of swine influenza adds a significant observation to research on viruses. In his most recent paper he¹ reports ninety-eight experiments with transmission, using 216 swine and involving a three year study of the lungworm as an intermediate host for the virus of swine influenza. Fifty of the experiments gave negative results. In the remaining forty-eight transmission of virus by way of the lungworm was demonstrated in 1 or more animals of each experiment. Irregularities in the results, Shope explains, would appear to be due not so much to lack of transmission of the masked virus by the lungworms as to failure to evoke its pathogenic capabilities. In several experiments pigs developed infections with the virus of swine influenza nine to seventeen days after infestation with infected lungworms, in the absence of any known provocative stress. An immune response of the swine to the lungworms themselves is suspected in these instances of having furnished the provocation. During the summer months May to August inclusive swine prepared by the injection of lungworms carrying virus were absolutely refractory to the provocation of influenza. They were also relatively refractory in September and October. Activation of the masked virus occurred most readily during the first four months of the year. In one experiment it was possible to demonstrate by direct means the presence of virus in the neighborhood of lungworms at the base of the lung at a time when the virus could not be demonstrated anywhere else in the respiratory tract. Masked virus of swine influenza was found to be present in lungworm ova obtained either from the respiratory tracts or from the feces of infected swine. In several instances masked virus persisted for over a year in lungworm larvae within the earthworm intermediate host, and in one of these its presence was demonstrated after thirty-two months. Finally it was found that lungworm ova obtained from convalescent swine which no longer carry swine influenza virus in infectious form in their respiratory tracts contain a masked virus. Such observations as these on the behavior of swine influenza virus are of doubtful immediate significance in relation to human influenza, though they clearly extend knowledge of the behavior of viruses. Furthermore swine influenza itself although not a highly fatal disease, has some intrinsic importance to the national economy and the veterinary profession.

1 Shope, Richard E. The Swine Lungworm as a Reservoir and Intermediate Host for Swine Influenza Virus. *J. Exper. Med.* 77: 111 (Feb.) 1943.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

RESTRICTIONS ON USE OF INTERNS AND RESIDENTS

Because the number of interns and residents available for the year 1943-1944 will be very limited, the hospitals of the United States will have to reduce the number of such personnel to approximately 50 per cent of the number they maintained in 1940, it is announced by the Directing Board of Procurement and Assignment Service, acting on the advice of its Committees on Hospitals and the Allocation of Medical Personnel.

The following recommendations have been issued by the Directing Board of the Procurement and Assignment Service to its state chairmen:

For the efficient utilization of attending physicians, interns and residents, hospitals should avoid duplication of activities such as two or more medical, surgical or other surgical services, by consolidating such parallel services into one.

Hospitals should be requested also to arrange for the reabsorption of clinics in the subspecialties into a general clinic of the parent specialty and to maintain within the structure of the medical staff, in both inpatient and outpatient services, only such specialties as are recognized by the Advisory Board for Medical Specialties.

A hospital should not have more interns on July 15, 1943 than the number on duty on July 15, 1940 unless it can be shown that the institution's patient load has definitely increased or that other conditions exist that merit special consideration. Hospitals which have had a decrease in their patient load since July 15, 1940 should make a corresponding decrease in the number of interns.

In order to provide an adequate background for military medical service, at the completion of one year of internship, hospitals which do not now maintain rotating internships should, for the duration of the war, broaden and diversify the instruction and experience of their interns.

A physician who is eligible for military service should not be approved as an essential resident in a hospital unless the residency concerned is approved by the appropriate crediting body.

A physician who is eligible for military service should not be approved as an essential resident in a hospital for longer than a period of one year immediately following the completion of his internship. Physicians who by age, sex, physical defect or citizenship status are disqualified for military service may serve as residents in hospitals for periods varying from one to three years after internship. After this period of service such physicians, if they are to be approved by the Procurement and Assignment Service as essential, must have been appointed as full time members of the regular medical staff.

After July 1, 1943 the total number of residents permitted for the hospitals of the United States shall not exceed 50 per cent of the number on duty in the hospitals on July 15, 1940, this 50 per cent shall include those residents who are not eligible for military service, e.g. women physicians, physically disqualified male physicians, older physicians and alien physicians.

In view of the considerable number of physicians not qualified for military service who should be available for appointment as hospital residents, all hospitals should fill as nearly 100 per cent as possible of their allotted residencies with physicians not eligible for military service.

The total number of residents which a hospital may be permitted to retain shall be directly related to that hospital's teaching and service responsibilities with particular reference to the proportion of its ward service to total service. Consideration of an individual resident should be based primarily on his teaching responsibilities and patient service load and not on any specialized service which he may render to individual members of the staff or to a particular hospital service. A hospital shall not be permitted to retain a greater percentage of the number of its residents which it had on July 15, 1940 than the percentage of its ward patient days in relation to its total patient days, except that a hospital shall not retain more than two thirds the number of the residents it had on July 15, 1940.

Ward service is defined as service to patients who are not charged or paying a professional fee and patients who are used for teaching demonstration, if a teaching program is being conducted. In computing the service load the volume of outpatient visits shall be given due consideration.

Primarily teaching hospitals, i.e. hospitals carrying major responsibility for undergraduate medical teaching, shall be given consideration for that service in addition to that which they receive on the basis of ward service. A hospital which has made radical changes in bed capacity or in its intern and residency plans or has lost an excessive proportion of its visiting staff since July 15, 1940 may receive special consideration in the number of residents it is permitted to retain.

The Central Office of the Procurement and Assignment Service shall determine the total number of residents to be allotted to each state and shall suggest for the guidance of the respective state chairmen the number of residents recommended for each hospital after July 1, 1943.

Hospitals which find it necessary to request permission to retain, for a residency, an intern who holds a commission in military service shall submit such request to the state chairman for physicians of the Procurement and Assignment Service, who will add his recommendations and forward it to the Central Office of Procurement and Assignment Service for action by the directing board and for recommendation by the Army and Navy.

As far as possible, physicians who hold reserve military commissions for whom requests for further deferment have been made shall be assigned to residencies which will provide training of greatest usefulness in their subsequent military service, e.g. in surgery or medicine rather than in obstetrics and gynecology.

In order to accomplish these objectives, all residents must be selected from the following groups:

- 1 Women physicians
- 2 Male physicians who have been officially rejected for commissioned service with the Army or Navy
- 3 Male physicians who have been classified 4 F by Selective Service
- 4 Physicians who have applied for commission in the Medical Corps of the Army of the United States or the Naval Reserve and whose deferments are being requested for the ensuing year, as outlined.

Hospitals should be instructed not to communicate with the Army or the Navy regarding deferment of reserve officers for further hospital service. Such communications should always be addressed to the state chairmen of the Procurement and Assignment Service.

PROCUREMENT OF SANITARY ENGINEERS

Paul V McNutt, chairman of the War Manpower Commission, has issued a directive placing the procurement and assignment of sanitary engineers for the armed forces and other governmental agencies under the War Manpower Commission's Procurement and Assignment Service for Physicians Dentists and Veterinarians

Plans are already under way to facilitate the recruitment of sanitary engineers by the armed forces without endangering public health by clearing all sanitary engineers through the Procurement and Assignment Service, as is done with physicians, dentists and veterinarians

A critical shortage of trained sanitary engineers exists as a result of the need of the armed forces for the services of these engineers who are trained in disease prevention and health protection, particularly in those parts of the world where the armed forces are encountering disease hazards resulting from improper sanitation and in many instances from insects peculiar to a particular region

To meet these needs of the armed forces, many of the state, county and local health organizations, as well as concerns employing sanitary engineers, have been heavily drawn on. To make the best use of the dwindling number of sanitary engineers for military, semimilitary and civilian purposes, it has been found necessary to establish a more uniform system of procurement and assignment of such professional personnel than has been applied up to this time. Accordingly, the War Manpower Commission has set up in the Procurement and Assignment Service for Physicians, Dentists and Veterinarians a Committee for Sanitary Engineers to be made up of the following members:

Abel Wolman, chairman, professor of sanitary engineering, the Johns Hopkins University, Baltimore

Kenneth F. Maxcy, professor of epidemiology, School of Hygiene and Public Health, the Johns Hopkins University, Baltimore

Harold E. Babbitt, professor of sanitary engineering, University of Illinois, Urbana, Ill.

F. C. Bishop, assistant chief, Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, Washington, D. C.

V. M. Ehlers, chief engineer, Texas State Board of Health, Austin, Texas

Gordon M. Fair, professor of sanitary engineering, Harvard University, Cambridge, Mass.

H. A. Whitaker, chief engineer, Division of Sanitation, State Department of Health, Minneapolis

Mr. Paul Hansen, consulting engineer of Chicago, has been appointed as civilian consultant. C. W. Klassen of the Army Sanitary Corps and formerly chief sanitary engineer of the Illinois State Department of Health, is being assigned by the Army to the War Manpower Commission to handle sanitary engineering procurement under Dr. Max Lapham, executive officer of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians.

For the purpose of administering this directive by the War Manpower Commission, the professional occupation designation "sanitary engineer" shall apply to a graduate of an approved scientific school who has fitted himself by suitable training or study and by experience to conceive, design, operate, direct or manage engineering works (a) developed as a whole or in part for the protection and promotion of the public health or (b) capable of injuring the public health through faulty conception, design, construction, operation or management. The basis for differentiation between individuals qualified as sanitary engineers and those qualified only as civil, mechanical, electrical, mining or chemical engineers shall be the ability to identify, evaluate and explain in terms of their sanitary or public health implications those factors connected with such engineering works as will prevent injury to health or will promote health in addition to the ability to conceive, design, operate, direct or manage such works.

All sanitary engineers coming within the scope of this occupational definition are urged to place their names on file with the War Manpower Commission and for this purpose and for any further information should communicate with the Procurement and Assignment Service, War Manpower Commission, 1006 U Street NW, Washington, D. C.

The functions of the Procurement and Assignment Service in regard to sanitary engineers will be:

1 To determine the military and civilian needs for sanitary engineering personnel for this country and abroad

2 To estimate the availability of sanitary engineering personnel of various ages and grades of experience

3 To establish a plan for a well balanced allocation as far as practicable to meet the civilian and military needs

PHYSICIANS' PREFERENCE IN CHOICE OF MILITARY SERVICE

A recent memorandum from the Officer Procurement Service of the War Department states that physicians, dentists and veterinarians are afforded an opportunity on the reply cards sent to them by the Central Office of the Procurement and Assignment Service to indicate a preference for service with the Army, including the Medical Department of the Army, Air Forces, or the Navy. Preference so expressed by a candidate for service with the Medical Department of the Army, Air Forces will be plainly indicated on form 97 by the state Procurement and Assignment chairman when that form is transmitted to a district office.

Effective immediately, each district office, in forwarding to the Surgeon General the completed papers of any candidate who has expressed a preference for Army, Air Forces service, will include therewith a clear statement that the candidate has expressed a preference for service with the Medical Department, Army, Air Forces.

District offices will not attempt to influence a candidate one way or the other. If there is no information in regard to preference on a candidate's form 97, the interviewing officer will not request information as to his preference. If a candidate requests information relative to assignments, the interviewing officer will inform him of his right to state, if he so desires, a preference. The district office is responsible for recording and forwarding the facts as to a candidate's preference, if any, in accordance with the foregoing.

In discussing assignments with candidates interviewing officers will at all times make it clear that while every consideration will be given to a candidate's expressed preference, there can be no assurance that he will receive the assignment requested. Assignments are based on the candidate's qualifications and existing needs.

THE QUOTA FOR DENTISTS

A wartime ratio of 1 dentist to each 2,500 civilian population has been established by the War Manpower Commission's Procurement and Assignment Service for Physicians, Dentists and Veterinarians in establishing state quotas for the 6,689 practicing dentists that will be required to meet the needs of the armed forces in 1943. The *Journal of the American Dental Association* reports: "The total needs of the armed forces for the current year will be 9,500 dentists. The Procurement and Assignment Service points out that 3,616 of these will be obtained from 1942 and 1943 dental graduates leaving 5,884 practicing dentists who will have to be obtained from the various states. In addition, 805 dentists still are to be inducted as of Nov. 30, 1942 to fill the quota for last year."

The Committee on Dentistry of the Procurement and Assignment Service reports that 1942 and 1943 dental school graduates who are commissioned in the armed forces are not to be credited against the quotas of the states in which they reside but against a central quota. The 5,884 dentists to be obtained among practicing dentists have been distributed in proportion to the dentists in each state. As of Nov. 30, 1942, thirty-two states had exceeded their first quotas by 1,283; however, Alabama, Arizona, Arkansas, Delaware, Florida, Georgia, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, Oklahoma, South Carolina, Tennessee, Texas and Virginia had contributed dentists in excess of the sum of their 1942 and 1943 quotas.

ARMY

THE BORDEN GENERAL HOSPITAL

The new U S Army Borden General Hospital at Chickasha, Okla., of 1,003 beds was completed on January 15. The buildings are of wood cantonment type construction with outside asbestos sheathing. The total number of buildings is 135, which includes the theater of operation type buildings and barracks for the numbered field hospital that will be attached. The hospital has been named in honor of the late Lieut. Col. William Cline Borden, distinguished officer of the Medical Corps.

The medical officers on duty at the hospital are as follows:

COLONELS

Ernest R. Gentry, Commanding Officer
William H. Gordon, Chief Medical Service

MAJORS

Clarence E. Bird, Chief Surgical Service
Edmond L. Faust, Assistant Chief Surgical Service
John B. Hunter, Surgical Service Assistant
Felix Jansev, Chief Orthopedic Section
Kerwin M. Marks, Chief Plastic Surgery Section
Leslie E. Morrisett, Chief E. E. N. T. Service
Nathan Muskin, Chief Section General Medicine no. 1
Leo V. Schneider, Chief Section General Medicine no. 2
Silas H. Starr, Chief Officers and Women's Section
Aloysius T. Waskowicz, Post Executive Officer

CAPTAINS

James B. Berardi, Chief Section on Cardiovascular Renal Diseases
Richard C. Cooke, Chief Neurology and Psychiatry Section
Karl D. Dietrich, Chief Septic Surgery Section
Leonard Freeman, Ward Surgeon
Sidney Gelman, General Medicine no. 2, Allergy, Acute Exanthematous Diseases
Samuel C. Gillespie, Officers and Women's Section
Kenneth G. Jahnus, Chief Anesthesia Section
James E. Kahler, Chief Laboratory Service
Frank Kaminsky, General Medicine no. 1
Miles I. Kelly, Mess Officer
Daniel M. Kingsley, Ward Officer, Orthopedic Section
Wilfrid J. Lewis, General Medicine no. 2, Dermatology, Syphilology, Acute Upper Respiratory Disease
Hirsch R. Liebowitz, Chief Gastroenterology Section
William J. MacFarland, Chief X-Ray Service
Francis L. McPhail, Ward Officer, Orthopedic Section
Arthur H. Milbert, Chief Urologic Section
Dolbert A. Minder, Ward Officer, Surgical Service
Ira S. Pidgeon, Ward Officer, Urologic Section
Cleon S. Rost, Ward Officer, Surgical Service
John W. Shadle, General Medicine no. 1, A. P. Section
Sanders K. Stroud, E. E. N. T. Assistant
Lee D. Van Antwerp, Registrar
George K. Weyer, Cardiovascular Renal Diseases
Harry T. Zankel, Chief Physical Therapy

FIRST LIEUTENANTS

Eugene W. Black, Anesthesia Section
Howard C. High Jr., E. E. N. T. Service
Oscar B. Hunter Jr., Assistant Chief Laboratory Service
Max E. Johnson, Neurology, Neuropsychiatric Section
William P. Parrilli, Neuropsychiatric Section
Allan E. Walker, Gastroenterology Section

The chief nurse is Capt. Helen A. Johnson of the Army Nurse Corps.

The medical officers on duty with the 49th General Field Hospital, attached are:

COLONEL

John L. Kantor, Commanding Officer

MAJOR

Isaiah A. Wiles, Executive Officer

CAPTAINS

Samuel S. Caplin
Frederick R. Mallott, Adjutant
Milton H. Omstead, Assistant Executive Officer

OFFICERS FROM THE RANKS

Companies C and D of the Medical Administrative Corps Officer Candidate School at the Medical Replacement Training Center, Camp Berkeley, Texas, graduated on March 24. Participating in the ceremony were Brig. Gen. Roy C. Heflebower, commandant, Col. George E. Armstrong, assistant commandant, Lieut. Col. Charles L. Driscoll, executive officer, and the band and color guard. Men selected from the ranks to attend officer

candidate school are chosen for their qualities of leadership, initiative and intelligence regardless of their educational background. On completion of an intensive twelve weeks training course these M. A. C. officers take over nonmedical functions formerly performed by medical and dental officers, thus releasing them for professional duties with field troops. On completion of a ten-day leave, the newly commissioned second lieutenants will report to their first station assignments.

GENERAL DAVIS VISITS HOSPITALS

Brig. Gen. Addison D. Davis, commandant of the Medical Field Service School, Carlisle Barracks, Pennsylvania, and Col. Albert S. Dabney, assistant commandant, returned on April 1 from a trip through the South and Midwest where they visited medical installations to observe the results of the courses of training for officers at the Medical Field Service School. At each station visited these officers sought out the Carlisle-trained officers who, during the training, the commanding officers of the various posts praised highly. At the Medical Replacement Training Center at Camp Robinson, Arkansas, they observed 101 graduates of the Officer Candidate School at Carlisle Barracks. Brig. Gen. James E. Bravis, commandant of the training center, said that the medical administrative corps officers exhibited training of a high order. General Davis and Colonel Dabney visited also six general hospitals, several station hospitals, a school for aviation medicine, a port or embarkation and a great medical supply depot. They observed that in many cases the station hospitals were larger than the general hospitals. The aim of the medical department to have all soldiers in the best possible health before going to theaters of operation, General Davis said, would keep to the lowest possible level the number who would eventually have to be treated in general hospitals. That view is corroborated in the present low disease rate not only in the homeland but in the actual theaters of operation.

WALTER REED HOSPITAL'S CONVALESCENT CENTER

A convalescent center for Walter Reed General Hospital has been opened in the buildings which were formerly the National Park College, a school for girls at Forest Glen, Md. The convalescent unit provides an additional 1,150 beds, bringing the total capacity of Walter Reed Hospital to 3,325 beds. Careful planning has resulted in the fullest use of the facilities of the girls' school, located in beautiful park grounds which provide extensive recreational facilities, a swimming pool, bowling alley, amusement hall, gymnasium and walks and drives through shady groves. The excellent chapel contains a pipe organ and two libraries for patients. The clinic facilities for physical therapy, occupational therapy and dental work are extensive. The commanding officer at Walter Reed General Hospital is Brig. Gen. Shelly U. Marietta, Assistant Surgeon General, who is also in command of the Army Medical Center. General Marietta has had a distinguished administrative and professional career dating back to 1910 when he first entered the military service.

MALARIA RECONNAISSANCE AND COMBAT UNITS

According to the *Army and Navy Journal*, the War Department reports that the medical department has established sixteen "reconnaissance" units and twenty-six "combat" units to control the spread of malaria. The "reconnaissance" units are engaged in survey activities, each unit consisting of a parasitologist, four technicians, four field collectors and three chauffeurs. Each "combat" unit has a quartermaster, engineer, eight noncommissioned officers and privates and three chauffeurs. The forty-two malaria control units are or soon will be, in operation in areas where malaria is prevalent. The War Department reported that remarkably few fatalities have been attributed to malaria to date, owing largely to the antimalarial instructions, equipment and treatment available to troops.

THE HAMMOND GENERAL HOSPITAL

The new U S Army Hammond General Hospital near Modesto, Calif, will eventually have a capacity of 2,000 beds. It is of the cantonment type and is equipped to give treatment in all types of cases admitted to a general hospital. Recently it was designated by the War Department as a hospital which will receive also patients requiring special chest surgery. (THE JOURNAL, March 27 p 1095)

The hospital was named in honor of Brig Gen William H Hammond a pioneer in the development of medical field service and field hospitalization and a Surgeon General of the army during the Civil War.

The commanding officer of the Hammond General Hospital is Col Luther R Poust, M C, and the executive officer Lieut Col U R Merikangas, M C. The chiefs of service now on duty are:

Medical Service Major Garnett Cheney, associate professor of clinical medicine, Stanford University School of Medicine, Stanford University, Calif.

Surgical Service Major George S Reynolds on the staff of House of Mercy Hospital and St Luke's Hospital Pittsfield Mass

Neuropsychiatric Service. Lieut. Col. Mark Ziefert, chief of psychiatric service, Brooklyn Hospital, Brooklyn.

Five Ear Nose and Throat Service Major Alfred Wachsberger
adjunct professor of otolaryngology New York Polyclinic adjunct oto
laryngologist Beth Israel Hospital New York

Outpatient Service Major Ralph F. Pray on the staff of Monterey County Hospital Salinas Calif

✓ Ray Service Major Marvin I Upper Staff St John's Burge and
Springfield (Mo) Baptist hospital

Laboratory Service Captain Russell Kerr pathologist Kansas City Mo

The other medical officers assigned to this hospital and their previous locations are

Major William M. Askew Jr. hospital inspector Auburn Ala. and
Capt H. F. Nachtmann registrar, resident University of Pennsylvania
Graduate School Philadelphia

Medical Service Major Benjamin Rubin South River, N J Capt
Peter Callahan Philadelphia Capt Edward Denerholz director of
maternal and child welfare department of health Chicago Capt F R
Maddison Tacoma Wash Capt Richard L Saunders dermatologist and
syphilologist Buffalo Lieut Vincent Bellafiore Brooklyn Lieut C C
Greene Jr intern Jefferson Medical College Hospital Philadelphia
Lieut Sidney Margulis resident Edward J Mover Memorial Hospital

Lieut Aaron Spierer New York

Surgical Service Major Dolan E Hodge urologist Billings Mont
Major Eurfray Jones Camp Hill Pa Major Manuel Pusitz orthopedic
surgeon Kansas Crippled Children's Commi sion and Capper Foundation
for Crippled Children Topeka Kan Major Helen K Wallace St Joseph
Mo Capt Edward Jones resident in urology Grady Hospital Atlanta
Ga Capt Allen Iihenthal Memphis Tenn Capt Arnold Ntegele
St Paul Minn Capt Carlton Price ob etrician and gynecologist
Rochester N Y Lieut Eli Bernstein surgeon Flint Mich Lieut
J F Bokovatz Fresno Calif Lieut E Davis Vincenttown N J, on
staff of Cooper Hospital Camden N J Lieut Abraham Klein New
York Lieut Frederick Luger on staff of St Mary's Hospital Saginaw
Mich and Lieut Harold B Miles resident in ane sthesia Methodist Hos
pital Indianapolis

Neuropsychiatric Service Capt H B Hargus medical director Twin
Pines Sanitarium Belmont Calif Psychiatrist San Mateo County
Hospital San Mateo Calif Capt W L Noe Lanham Pr on staff
of Abington (Pa.) Memorial Hospital Lieut Roger Dixon administra
tive psychiatry Elwyn (Pa.) Training School and Lieut E R Miller
Mercy Hospital San Diego Calif

Eve Ear Nose and Throat Service. Capt N H Battles on staff of latter Dr. Saints Hospital and Idaho Falls Sacred Heart Hospital Idaho Falls Idaho. Capt Michael Lewin plastic surgeon on staff of Sydenham and Mount Sinai hospitals N Y and Capt James E Reeder on staff of Lutheran Hospital Sioux City Iowa.

NAVY

MEDICAL SPECIALISTS UNIT NO 110

Naval Medical Specialists Unit No 110, organized at the Cleveland Clinic (Ohio), reported for duty at the Naval Medical Supply Depot in Brooklyn in March 1942 in connection with the establishment of Naval Mobile Hospital No 4 of several hundred beds which could be set up in a short time on arrival overseas. The material included seventy prefabricated metal buildings, equipment and supplies for the numerous departments of a hospital, even fire fighting apparatus, laundry, power and light, refrigeration and water supply. The personnel was to comprise about 20 medical and dental officers and 180 enlisted men. The original complement of officers from Cleveland comprised Lieut Comdr J R Kennedy, ophthalmologist and otolaryngologist, Lieut Comdr J C Root, roentgenologist, Lieut Comdr A C Ernstene, internist, Lieut Comdr W James Gardner, neurologic surgeon, Lieut Comdr W J Engel, urologist, Lieut Comdr D H Nichols, dentist, Lieut George Crile Jr, surgeon, Lieut Guy H Williams Jr, psychiatrist and Lieut (jg) E J Ryan, clinical pathologist. While waiting for the hospital to be assembled before embarkation the following additional medical officers, several of whom had taken post-graduate training in Cleveland, arrived: Lieut Hays R Yandell, Lieut Gordon Sinclair, Lieut Ray Andrews, Lieut Ralph Zupaneck, Lieut (jg) George Berry (DC), Lieut Charles Bingham, Lieut Comdr Dennis O Connor, Lieut (jg) Royston Miller, Lieut Burnell Eckart, Lieut Comdr Russell H Blood and Lieut (jg) Fred Sanborn.

The commanding officer, Capt John H Robbins M C U S Navy, and Lieut Comdr W James Gardner M C U S Naval Reserve were detached from the unit and sent to New Zealand to make preliminary arrangements for the establishment of the hospital. Lieut Comdr Gardner describes the trip across the Pacific in the Bulletin of the Academy of Medicine of Cleveland and the environment in which the hospital was eventually established. The site selected was a hockey field of several acres about 3 miles from Wellington. The setting up of this hospital in a new country he says, was a remarkable accomplishment, done largely by untrained hands, but in one month from the day work started the wards operating rooms mess halls and x ray department were ready to function, and on that day 366 casualties were received from the landing operations in the Solomons. Within two months the hospital had

received more than 1,200 wounded of whom only 1 died. The hospital was then enlarged to 1,000 beds by adding wards built of New Zealand materials and by local labor. The complement of medical officers on the staff then was doubled. Lieutenant Commander Gardner in the fall returned to San Francisco with a large group of the wounded and later he says was transferred to inactive duty. When he left the outfit in Wellington all the men were in excellent health.

EPIDEMIC CONTROL SPECIALISTS

Thirty-four officers and fifty-eight hospital corpsmen were graduated on April 3 as epidemiologists in a ceremony held at the National Naval Medical Center Bethesda Md. The graduates were addressed by Rear Admiral Luther Sheldon Jr., assistant chief of the Bureau of Medicine and Surgery. These doctors, technical specialists and enlisted men have been divided into epidemiologic teams for assignment to naval stations, marine amphibious forces and overseas bases where they will maintain sanitary conditions and guard against outbreaks of disease. Within the continental limits these teams will be composed of two officers and four hospital corpsmen; in overseas activities the composition will vary depending on local conditions and the character of the unit to which the team is attached. A new class will start training on April 19 at the Naval Medical School.

EXAMINATION FOR APPOINTMENTS IN THE NAVAL MEDICAL CORPS

The next examination for appointments as acting assistant surgeons for intern training and for assistant surgeons United States Navy, will be held at all of the major naval hospitals on May 3 to 7 inclusive. To date more than two hundred applications have been approved for these examinations.

INSTRUCTION IN MALARIOLOGY

A class of six medical officers was convened at the Naval Medical Center, Bethesda, Md, on April 15 for a course of instruction in malarialogy. Seventy-two members of the Naval Hospital Corps and H-V(S) officers will also be convened for instruction in malarialogy and epidemiology on the same day.

MISCELLANEOUS

MEDICAL ATTENDANTS FOR MERCHANT SHIPS

A new school has been established at the Sheepshead Bay Training Station of the War Shipping Administration for the intensive training of medical attendants to serve on merchant ships. The 250 men enrolled as apprentice seamen of the Maritime Service who graduated from the school on March 12 will rate as petty officers responsible to the ship's master for the handling of health and sanitary problems. The school, which is under the supervision of the U. S. Public Health Service and under the immediate charge of Dr. S. S. Heilweil, has a staff of instructors and nurses, laboratories, lecture halls, sound film projection and other equipment necessary for the three months intensive course on sanitation, disease prevention, personal hygiene, first aid, transportation of the sick and injured, nursing and elementary pharmacy. This plan is said to be the first to provide every merchant ship, including cargo freighters, with a seaman trained and equipped to handle sanitary and health problems on board. The course is limited to men between 18 and 25 years of age with high school education.

NYLON SURGICAL SUTURES

Nylon has proved to be a superior replacement for silk in surgical sutures according to du Pont de Nemours and Company, Inc., and millions of feet of nylon monofilament that formerly went into tennis racquet strings and other things will replace silk this year in surgical sutures for the army and navy and civilian use. Nylon will not dry out and rot like the natural fiber and it has greater tensile strength than silk. The monofilaments are solid strands in contrast to silk sutures, which are made by twisting together a number of threads. The nylon sutures are noncapillary, and bacteria cannot travel through them as they sometimes do in braided material, furthermore being smooth and solid, skin cannot grow into the interstices as it sometimes does in the interstices of silk sutures causing irritation and other complications when the sutures are removed. Nylon can be used internally as well as externally.

PRIORITY FOR MATERIAL FOR PRODUCTION OF HEALTH SUPPLIES

Since adequate priorities assistance for materials for the manufacture of health supplies is now assigned by other means, preference rating order P-29, formerly used for this purpose, has been revoked by the War Production Board. The revocation includes all serially numbered copies of P-29 and is effective immediately.

P-29, issued in August 1941, was formerly used for priorities assistance to manufacture surgical and dental instruments, x-ray equipment, biologic products, medicinal chemicals and other commodities in the health supply field.

Application for priority assistance in obtaining controlled materials and other materials necessary to complete authorized production schedules under CMP should now be made on form CMP-4B. Application for chemicals, biologic products and other miscellaneous items should be filed on form PD-1A.

ARMY-NAVY E AWARDS

The Army-Navy E Production Award was presented to the employees to the Baxter Laboratories, Inc., Glenview, Ill., at the public school auditorium in that community, March 11. The Baxter Laboratories are well known manufacturers of intravenous solutions and blood plasma and serum equipment.

James King & Sons, Inc., New York City, were awarded the Army-Navy E at ceremonies in the auditorium of the new Halloran General Hospital at Willowbrook, Staten Island, New York, which is said to be the largest army hospital in the United States. The ceremony was presided over by Supreme Court Justice John H. McCooey of Brooklyn and was attended by army and navy officers and hundreds of the employees of the company, who were praised for the speed and efficient manner in which the hospital was built. E pins also were presented to employees of the company.

PUBLIC HEALTH UNDER HITLER

By a decree published in the Reichsgesetzblatt, the fuhrer has entrusted the German Red Cross (DRK) with the entire transport of the sick in the sphere of civilian health services. According to DNB of January 23, he has, moreover, ordered the reich health leader Dr. Conti, to issue the executive regulations in conjunction with the fuhrer's delegate for medical and health services Prof. Dr. Brandt. The new scheme, resulting from the fuhrer's decree and the reich health leader executive order, represents progress in the work of the health services. Numerous organizations have hitherto dealt with the transport of the sick, and their activities have not been sufficiently coordinated. This has often made a uniform control of the transport of sick persons difficult. In many places, especially in the country, this work has already been carried out exclusively by the DRK. Those organizations which are at present still engaged in the transport of the sick will now inform the DRK of their facilities for this work which they will on request transfer to the DRK for a corresponding compensation fixed in accordance with the Reich Compensation Law (Reichsentschädigungsgesetz). Likewise the personnel who have hitherto transported sick persons, while maintaining their present rights must, on request, be made available for incorporation into the DRK. The DRK will immediately start setting up the DRK Transport of the Sick and will announce locally when it is going to take over the entire transport. Until then the organizations at present engaged in the transport of the sick are to carry on. The DRK however may give them instructions. The new regulations do not affect the transport of the sick of the armed forces, the Waffen SS, those parts of the police which are subordinated to the armed forces, the Reich Labor Service and the Todt Organization.

The Leipzig *Völkische Nachrichten* of Nov. 29, 1942 reports that Saxony holds a leading place among all districts with regard to health services in factories. For instance, the number of industrial doctors has risen from 90 to 600 since the beginning of the war. It is now recognized as necessary to provide the factory health wardens with the necessary technical knowledge. In the Knapp health resort of Bergschnebel courses lasting a fortnight have been held. Men and women from the most important industrial concerns are here to learn, part in the training and at the same time are guests with full rights to use all facilities of the spa. They get their knowledge from practical experience on their own body. Early in the morning they get their ablutions and compresses according to a plan of treatment ordered by the doctor, and as their training proceeds they help one another with their treatment. Then follow lectures and practical demonstrations beginning with compresses for the chest and finally those for the whole body, ablutions, herb baths and other baths of all kinds. These factory health officials are not meant to give regular treatment but are rather expected to pass on their knowledge and above all, to set an example by their own natural way of living and to educate their fellow workers in it.

According to the *Krakauer Zeitung* of Nov. 19, 1942 the German Hospital, which has been extended and reconstructed, has now been handed over to Dr. Wiggers. It consists of five departments: the department for internal diseases, the surgical department, the department for skin and venereal diseases, the gynecologic department and maternity post, and an x-ray department. These departments, with the exception of the department for skin and venereal diseases, also treat outpatients. All departments are under the direction of specialists. The maternity post is to be transferred to the municipal maternity hospital, where a special department for German women is to be opened. The German Hospital of Lwow will be extended by a children's hospital. The admission to the German Hospital is subject to the regulations issued by the general government. Only the reich German and German speaking *volksdeutsche* are admitted.

Radio Paris of February 11 reported that hospital train No. 528 arrived, February 10, at the Gare de Lyon, Paris, from Germany with 384 patients, who were sent to three different hospitals.

ORGANIZATION SECTION

OFFICIAL NOTES

DOCTORS AT WAR

Radio broadcasts of Doctors at War by the American Medical Association in cooperation with the National Broadcasting Company and the Medical Department of the United States Army and the United States Navy are on the air each Saturday at 5 p m Eastern War Time (4 p m Central War Time, 3 p m Mountain War Time, 2 p m Pacific War Time). An exception is the Chicago area, where the broadcasts are heard by transcription at 10 30 p m Saturdays over Station WMAQ. Unless otherwise indicated, each program is summarized by Dr W W Bauer, Director, Bureau of Health Education.

The titles and guest speakers for the next four programs are as follows:

- April 24 Sharp Eyes
Speaker: Lieut Col Harold C Lueth
Liaison Officer, Surgeon General's Office and A M A
United States Army
- May 1 Jungle Death
Speaker: Brig Gen C C Hillman
Chief of the Professional Services Office of the Surgeon
General, United States Army

- May 8 Drugs March to War
Speaker: Dr Austin E Smith, Secretary,
Council on Pharmacy and Chemistry
- May 15 High Air

BEFORE THE DOCTOR COMES

The American Medical Association program on Radio Station WLS (890 kilocycles) entitled "Before the Doctor Comes" will be on the air every Thursday morning at 9 45 up to and including May 27. Mrs June Merrill will interview Dr W W Bauer, Director, Bureau of Health Education, or Dr Austin E Smith, Secretary, Council on Pharmacy and Chemistry, on common home health problems. The titles for the next four programs are:

- April 22 What to Do About Bad Bumps
(Bauer)
- April 29 What to Do About Bleeding
(Bauer)
- May 6 What to Do About Foreign Bodies in the Nose
Ears, Throat or Eyes
(Smith)
- May 13 Growing Pains
(Bauer)

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H R 1857 has passed the House and Senate, providing for the appointment of female physicians and surgeons in the Medical Corps of the Army and Navy.

Bills Introduced—S 939, introduced by Senator Pepper, Florida, proposes a federal appropriation of \$11,580,000 for each fiscal year to enable each state to establish, extend and improve services for educating physically handicapped children. The sums to be made available will be used in making payments to those states which have submitted and had approved by the United States Commissioner of Education plans for the services indicated. S 983, introduced by Senator Bailey, North Carolina, would authorize such sums as may be necessary to provide for the training of nurses for the armed forces, governmental and civilian hospitals, health agencies and war industries, through grants to institutions providing such training. This bill is identical with H R 2326, introduced by Representative Bolton. Both bills were introduced at the suggestion of the Administrator of the Federal Security Agency. H Res 202, submitted by Representative Shafer, Michigan, will, if adopted, direct the House Committee on World War Veterans' Legislation to make a survey of existing veterans and military hospital facilities and a survey of the needs arising, and likely to arise, from the existing emergency for medical, tuberculosis and mental hospitals for veterans. The committee will be directed to submit to the House of Representatives a report covering a general program, with estimates of the cost, for the provision of hospital facilities likely to be needed. H R 2383, introduced by Representative Chapman, Kentucky, proposes to amend the Insecticide Act so as to provide that any white powder insecticide or fungicide containing arsenic in its elemental form or in any of its combinations, or fluorine in any of its combinations, shall, unless deemed unnecessary by the Secretary of Agriculture for the protection of the public health, be deemed to be adulterated unless it is distinctly colored in accordance with regulations promulgated by the Secretary of Agriculture. H R 2442, introduced by Representative Sparkman, Alabama, provides that during the present emergency and for six months

thereafter the Chief of the Dental Division, Surgeon General's Office, Army of the United States, shall have the rank, pay and allowances of major general. The bill provides too that there shall be officers of the Dental Corps promoted to the grade of brigadier general at the ratio of one for each six officers of the Medical Corps promoted to like grade.

STATE MEDICAL LEGISLATION

California

Bills Introduced—A 686, to amend the Health and Safety Code, proposes, among other things, that the state director of health shall be a doctor of medicine eligible to license to practice in California, with at least one year's postgraduate training in public health and a minimum of five years' practical experience as an administrative officer in a well organized health department. A 1335 to amend the law relating to the use and sale of poisons, proposes, among other things, to add the following poisons to schedule C1: acetylurea, sulfonated methanes, paraldehyde, sulfanilamide except in tablets of 30 grains or more designed for stock purposes only and so labeled, sobisminol, amidopyrine, cinchophen, ergot, diethylstilbestrol provided that they may be sold only at retail on order or prescription of a physician, dentist, chiroprapist or veterinary surgeon duly licensed to practice in the state of California and shall not be refilled without order of the prescriber to schedule C2: amphetamine, thyroid, phenylhydantoin or their compounds, provided they are sold only at retail on the written order or prescription of a physician and surgeon, dentist, chiroprapist or veterinary surgeon licensed to practice in the state of California but such prescription may be refilled for the person for whom originally written.

Colorado

Bills Enacted—H 199 was approved, March 31. To amend the chiropractic law, it requires chiropractors, at the time of the annual renewal of their licenses, to present proof that they have attended at least three days of a scientific clinic forum or educational study approved by the Colorado state board.

chiropractic examiners H 200 was approved, March 31. It authorizes the chiropractic board to adopt a schedule of minimum educational requirements for chiropractic schools to be not less than 3 600 sixty minute hours of classroom instruction with a maximum of thirty hours per week.

Connecticut

Bills Introduced—Sub for S 562 proposes to authorize a town board of education to appoint one or more legally qualified practitioners of medicine as school medical advisers and to provide such medical advisers with adequate facilities to provide for private health examinations of individual pupils. H 1194, to authorize a town health officer to detain and examine persons reasonably suspected of being infected with a venereal disease, has had an amendment to it introduced which would provide that nothing therein should be construed to interfere with the freedom of any adherent of the teachings of a well recognized religious sect, denomination or organization to depend exclusively on prayer for healing in accordance with the teachings of such sect, denomination or organization.

Georgia

Bill Introduced—S 213 proposes to require the secretary of state to issue licenses to practice naturopathy in Georgia to all persons who have been engaged in such practice in Georgia for the past three years and who have a license so to practice in the state of South Carolina. This proposal died in the Senate.

Bills Enacted—H 136 has become Governor's Act No 346 of the Laws of 1943. It requires all licensed physicians attending a pregnant woman to take a sample of blood within thirty days of the first examination and to submit such sample to an approved laboratory for a serologic test for syphilis. The title to this bill indicates that the word "physician" wherever used in the act shall be construed to embrace and include those persons licensed to practice under the osteopathic laws of Georgia. H 552 has become Governor's Act No 462 of the Laws of 1943. It abolishes the state boards of medical examiners, chiropractic examiners and osteopathic examiners and creates in their stead a State Commission of Medical Examiners, Georgia Commission of Chiropractic Examiners and State Commission of Osteopathic Examiners of Georgia. The powers, duties and qualifications of the new commissions are the same as those of the prior boards except that members thereof appointed by the governor must be approved by the secretary of state and confirmed by the senate.

Illinois

Bills Introduced—S 244 and H 393 propose to provide for the establishment and maintenance of county and multiple county public health departments. H 370 to amend the unemployment compensation act proposes that an employee will not be ineligible for benefits if he is unable to work because he is sick and has submitted proof of such sickness by means of a statement by a duly licensed physician. H 390 proposes to authorize the department of registration and education to issue licenses to practice physiotherapy defined as the method, art or science of treating the human body for hygienic or remedial purposes by the following methods: massage and manipulations with the hands or with any other physiotherapy modality, and the use of such adjuncts as light, heat, air, water, diet, gymnastics and electricity. H 395 proposes to authorize any town or two or more adjacent towns to be organized into a public health district.

Iowa

Bills Introduced—S 370, to amend the premarital examination law, proposes to permit a licensed physician who is a member of the armed forces of the United States, and authorized to make tests and examinations for syphilis to execute the required certificate for an applicant who is likewise in the armed forces. S 371, to amend S 82 concerning the income tax law which was approved by the governor March 11, 1943, proposes that a taxpayer may deduct expenses paid during the taxable year, not compensated for by insurance or otherwise, for medical care of himself, his spouse or any dependents. The term 'medical care' is defined to include amounts paid for the

diagnosis, cure, mitigation, treatment or prevention of disease or for the purpose of affecting any structure or function of the body and also treatment or nursing as prescribed by a well recognized church or religious denomination in any hospital or at home or in a sanatorium conducted and operated by such church or denomination.

Maine

Bill Passed—H 1352 passed the senate, April 5. To amend the law relating to infectious and communicable diseases, it proposes that every physician shall within forty-eight hours of the time the fact comes to his knowledge, report in writing to the state bureau of health any person known by and physician to have any of the following infectious and communicable diseases: syphilis, gonorrhea, chancroid and lymphogranuloma venereum. The proposal would also authorize the state bureau of health to detain and examine any person believed to be infected with one of the aforementioned diseases and so conducting himself as to expose others to the dangers thereof.

Bills Enacted—S 457 became chapter 236 of the Laws of 1943. It amends the act relating to procuring or attempting to procure an abortion or miscarriage by exempting therefrom those instances in which the abortion or miscarriage is necessary for the preservation of the mother's life. H 325 has become chapter 273 of the Laws of 1943. It authorizes the state board of registration of medicine to issue temporary emergency certificates by general regulations or specific orders to such physicians licensed outside the state as it shall find qualified to practice in the state of Maine during the emergency period, for the time specified in the temporary license and in the rules limited thereby. H 1202 has become chapter 195 of the Laws of 1943. It authorizes cities and towns to raise money for the purpose of subsidizing a physician to induce him or her to settle in said town.

Massachusetts

Bills Introduced—H 727 proposes to authorize a physician registered under the general laws to furnish contraceptives to a married woman in any case in which, after diagnosis, such physician is of opinion that her health or life would be endangered by pregnancy. H 1462 appendix H, to amend the narcotic act, proposes to add morphine to the list of drugs covered by the law.

Minnesota

Bill Introduced—H 1361 and S 1250 to amend the basic science law proposes that during the war and while accredited medical schools are accelerating their courses, the board of examiners may give examinations to applicants who are registered students in an accredited medical school and who are otherwise qualified even though such applicant is not 21 years of age.

Bill Enacted—S 825 has become chapter 314 of the Laws of 1943. To amend the law relating to coroners, it provides that any coroner or deputy coroner who is a duly licensed and registered physician and surgeon shall not be disqualified from rendering medical care or hospitalization to a recipient of public relief, from being appointed an examiner in insanity or incompetency hearings or from being compensated therefor.

Missouri

Bill Introduced—H 85 proposing to define the words physician and surgeon so as to include osteopaths and to authorize such persons to practice in government supported hospitals was amended in the house so as to provide that the right to practice in such hospitals would devolve on and be enjoyed by only such practitioners as have acquired education, experience and training of a standard equivalent to that required by the board of trustees of the hospital.

Nebraska

Bill Enacted—Bill No 149 was approved March 29. It exempts from the payment of the annual renewal license fee chiropractors, osteopaths and physicians while actively engaged in the military service of the United States as defined in the Soldiers' and Sailors' Civil Relief Act.

New Hampshire

Bill Passed—H 267, as amended by the house committee, passed the house March 30. It proposes the licensing of physiotherapists who have been engaged in the practice of physiotherapy for at least one year prior to the passage of the act.

New Jersey

Bills Passed—S 68 and S 72 passed the senate March 30. Both proposals would exempt from a law requiring compulsory vaccination for smallpox and diphtheria those persons who present an affidavit that vaccination violates a tenet of the established religious society, institution, organization or sect of which he is a member. A 276 passed the house, April 1. To amend the medical practice act, it proposes to exempt from the provisions thereof chiropractors while operating under the specific direction of a regularly licensed physician or surgeon.

New Mexico

Bill Introduced—Senate substitute for S 141 proposes that every physician who makes a diagnosis of or treats or prescribes for a case of venereal disease shall report such case immediately to the municipal or district health officer and authorizes state, district and municipal health officers to detain and examine persons reasonably suspected of being infected with a venereal disease and to require persons so infected to report for treatment to a reputable physician.

New York

Bills Enacted—C C H S 16, adopted, March 20, enacts a resolution to the effect that a legislative committee be appointed to make a comprehensive and thorough study of legislation enacted in other states for the regulation, control and licensing of chiropractors, to determine proper educational standards and requirements, and to prepare and recommend legislation for the regulation and licensing of chiropractors in New York. A 335 has become chapter 294 of the Laws of 1943. It authorizes the state commissioner of health to employ necessary medical and health personnel for rendering services in areas designated by the governor as being emergency health and sanitation areas by virtue of an inadequacy of medical facilities or personnel therein. Compensation to such employed medical personnel may be paid by the state department of health. A 1125 has become chapter 193 of the Laws of 1943. It amends the medical practice act by postponing until July 1, 1944, the 1942 amendment exempting students, interns and resident physicians from the operation of such act.

North Dakota

Bills Enacted—S 77 was approved, March 20. It provides for the establishment, maintenance and duties of a district board of health and provides that the district health officer appointed by such board shall be a physician and surgeon regularly licensed to practice medicine and surgery in the state of North Dakota. H 229 was approved, March 12. It provides for the organization and regulation of nonprofit hospital service plan corporations.

Ohio

Bills Introduced—S 237 proposes to provide a comprehensive program for the physical rehabilitation of war veterans. H 345 proposes the creation of a state board of chiropractic examiners. Chiropractic is not defined by the proposal, but the bill would prohibit a chiropractor from practicing major surgery or obstetrics or administering general anesthetics until he shall have passed an examination in those subjects given by the state medical boards.

Bill Passed—Substitute for H 112 passed the house, March 30. It proposes to amend the law relating to osteopathy by providing for one osteopathic member of the medical examining board and requiring osteopaths to be examined by such board in the subjects of anatomy, physiology, pathology, chemistry, and diagnosis, surgery, obstetrics and such other subjects as the board requires and by the osteopathic member in the subjects of materia medica and therapeutics and the principles and practice of osteopathic medicine. Successful applicants would be entitled to practice osteopathy and surgery. Persons now licensed to practice osteopathy but who have not passed an

examination before the state medical board would be allowed to continue to practice osteopathy and minor and orthopedic surgery but not to practice major surgery.

Oklahoma

Bill Enacted—H 222 was approved March 24. It amends the medical practice act by providing among other things, that the members of the board of examiners must be citizens.

Oregon

Bills Enacted—S 284 was approved, March 29. It authorizes the payment of workmen's compensation to employees disabled by an occupational disease defined as (1) any disease or infection which is peculiar to the industrial process in which the employee is engaged and which arises out of and in the scope of the employment, and to which the employee is not ordinarily subjected or exposed other than during a period of regular actual employment, (2) silicosis—meaning a disease of the lungs caused by breathing silica dust (silicon dioxide) producing fibrous nodules distributed through the lungs and demonstrated by x-ray examination or by autopsy. H 229 has become chapter 402 of the Laws of 1943. It reenacts and extends the existing law providing for state reimbursement to hospitals for services rendered victims of motor vehicle accidents so as to cover nurses, doctors and owners and operators of ambulances as well. H 350 has become chapter 218 of the Laws of 1943. It authorizes commissioned medical officers of the army to execute the certificate necessary under the state premarital examination law.

Pennsylvania

Bills Introduced—S 209, to amend the osteopathic law, proposes, among other things, to require the board of examiners by inspection or otherwise, to examine and fix the rating of all colleges and hospitals outside the state whose graduates or interns desire to obtain osteopathic licensure in Pennsylvania. S 460 proposes the creation of a state board of naturopathic education and licensure and defines naturopathy as a system of treatment and prevention of body ills without the use of drugs or surgery including in its armamentarium such natural elements as air, light, heat, electricity, water, phytotherapy, diet and/or physiologic and psychologic dysfunctions of the human body provided that nothing in the proposal would be held or construed to authorize any naturopathic physician licensed thereunder to use drugs or surgery. H Res 45 proposes a resolution to the effect that the department of health should initiate a campaign of education in order to bring home to the people the advisability and necessity of new immunization against disease and that the department through its county boards should make available sufficient serums and vaccines to properly guard the people against disease. H 669, to amend the law regulating and supervising nonprofit medical service corporations, proposes that subscribers earning more than a certain specified sum shall be liable to doctors of medicine registered with the corporation and rendering services to such persons for the full amount of the usual fees and charges for such services made by doctors of medicine and any payment made by the corporation to doctors for rendering such services shall be a payment on account and not necessarily in full. H 673, to amend the law relating to occupational diseases, proposes to include within the meaning of the term "occupational disease" infection or inflammation due to bacterial or parasitic agents in any occupation involving direct contact with or exposure to such agents. H 893 proposes the creation of a state board of chiropractic examiners and defines chiropractic as the science of treating human ailments by manipulation and adjustment of the spine of the human body and adjacent tissues thereof and the use of such mechanical, physiotherapeutic, dietetic, hygienic and sanitary measures except drugs and surgery, as are incident to the care of the human body, as taught and practiced in approved schools and colleges of chiropractic.

Bill Enacted—H 236 has become act No 8 of the Acts of 1943. It provides that for the duration of the war a minimum of nine months rather than one year internship shall constitute the necessary training to qualify for admission to examination for a license to practice medicine.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Acting Health Officer of Los Angeles County—Dr Hubert O Swartout, director of the bureau of preventable disease in the Los Angeles County Health Department, has been appointed acting health officer of the county. Dr Wilton L Halverson, Sacramento director of the department, was recently appointed in charge of the state department of health.

The George Dock Lecture—The annual George Dock Lecture of the Barlow Society for the History of Medicine was delivered by Dr George Blumer David P Smith clinical professor of medicine emeritus, Yale University School of Medicine, New Haven, April 2, at the Los Angeles County Medical Association. His subject was 'Remarks on the Life and Accomplishments of William Heberden the Younger.' The lecture marked the eighty-third birthday of Dr Dock.

Lillian Jane Martin Dies—Lillian Jane Martin Ph.D., emeritus professor of psychology at Stanford University, died at her home in San Francisco, March 26, aged 91. Dr Martin was born in Olean N.Y., July 7, 1851, receiving an honorary doctor of philosophy degree from the University of Bonn in 1913. She was a member of the department of psychology at Stanford from 1899 to 1916, when she became emeritus professor. Consulting psychologist in San Francisco and psychopathologist and chief of the mental hygiene clinic at the San Francisco Polyclinic and Mount Zion Hospital since 1916, Dr Martin was founder and director of the Old Age Center in San Francisco and president of the California Society of Mental Hygiene from 1917 to 1921. The New York Times credits Dr Martin with being the founder of the first child guidance clinic in the country. She was a member of many scientific societies and the author of extensive writings in her specialty.

State Medical Meeting—The seventy-second annual session of the California Medical Association will be held at the Biltmore Hotel, Los Angeles, May 2-3, under the presidency of Dr William R Molony Sr, Los Angeles. Among the out of state speakers will be

Dr John H Fitzgibbon, Portland, Ore, Wartime Community Health Problems in Oregon
John R Mannix, Detroit, director Michigan Hospital Service Voluntary Nonprofit Health Plans
Dr Tom D Spies, Cincinnati and Birmingham Ala, Detailed Methods of Diagnosis and Therapy in Acute Nutritive Failure
Dr William A Sawyer, Rochester N.Y., Some Medical Problems in Wartime Industry
Philip Drinker, Chem E, Washington D.C., Health Control in Welding Work
Dr John H Hutton, Portland, Spinal Anesthetic Agents and Methods Usually Employed at the University of Oregon Medical School Hospitals
Lieut H L Gartshore, M.C., Army of the United States, Pendleton Ore, Psychiatry at an Air Base Station Hospital

The program also includes a wide range of subjects to be presented by military and civilian physicians.

CONNECTICUT

Premarital Blood Test Law Amended—Out of state physicians and osteopaths are now eligible to sign marriage applications in Connecticut under a bill signed by the governor March 18. The act permits any physicians or osteopaths duly licensed in any state or territory of the United States or in the District of Columbia to sign a statement for marriage license application in Connecticut. According to the state department of health, the action is expected to relieve present difficulties, particularly on the part of men in the armed forces who are stationed in various sections of the country and desire to be married in Connecticut.

The Yale Poliomyelitis Study Unit—The National Foundation for Infantile Paralysis has made a five year grant totaling \$150,000 to Yale University School of Medicine, New Haven, to establish the Poliomyelitis Study Unit. The term of the grant will be from June 30, 1948. In 1941 the Yale Poliomyelitis Study Unit was established by Drs James C D Trask, New Haven as a result of problems which had been swept New England had begun to develop a virus members investigating

transmitted. The school of medicine will reorganize its investigation of poliomyelitis problems. Henceforth studies will be conducted in the Poliomyelitis Study Unit under the direction of Dr Paul, professor of preventive medicine, who will have administrative direction of the unit. An advisory committee of the National Foundation will be appointed by Mr Basil O'Connor, New York, president, to consult with Dr Paul and his associates as the need arises. As far as facilities permit, the foundation may send to the unit individuals properly qualified in the opinion of the foundation's medical advisory committee, to pursue definite lines of investigation. To meet the immediate needs of the study unit space will be arranged by the Yale University School of Medicine. None of the funds granted by the National Foundation for Infantile Paralysis will be used for the construction of new buildings.

Lectures on Non-War Psychiatry—A series of lectures was given recently at the Graduate Club of the Neuro-Psychiatric Institute of the Hartford Retreat, Hartford. The series was devoted exclusively to non-war neurology and non-war psychiatry.

Dr Foster Kennedy, New York, (a) Neurological Examinations, (b) Gait, the Midbrain, Myasthenia, (c) Myotonic Myasthenia and Other Neurological Conditions
William T. Liberson, Hartford, Psychiatric Research in Electroencephalography
Dr Abraham A Brill, New York, Various Schools of Psychotherapy
Dr Abraham Myerson, Boston, The Philosophy of Psychotherapy
Dr William H. D. Boston, Early Schizophrenia
Douglas H. Fryer, Ph.D., New York, Research Observations in Pre-pituitary Muscular Activity in Relation to Work
Dr Clarence B. Farrar, Toronto, An Editor Looks at the Psychiatric Literature
Dr Edward A. Strecker, Philadelphia, Alcoholism, Something on Therapy in Alcoholism Conditions
Dr Charles Macfie Campbell, Boston, Common Sense in Psychiatry
Dr Harold G. Wolff, New York, Emotions and Disease
Dr Donald J. McPherson, Boston, Relationship Between the Referring Man and the Mental Hospital

FLORIDA

Graduate Department of Medicine Organized—A department of medicine has been established in the Graduate School of the University of Florida, Gainesville. The new unit will be located in Jacksonville and maintained in cooperation with the state medical association and the state board of health. Dr Turner Z. Cason, Jacksonville, will be in general charge as director of the department. The new unit, which will conduct graduate courses and promote research in medicine and surgery, is the outgrowth of the annual graduate short course for doctors of medicine inaugurated about ten years ago. Continuation courses for practicing physicians with facilities for clinical instruction will be given from time to time.

ILLINOIS

Dr Brokaw Named Acting Director of Health District—Dr Raymond V. Brokaw, Springfield, chief of the division of cancer control, state department of public health, has been named acting director of the Champaign-Urbana Public Health District, effective March 16. He has succeeded Reuben F. Reider, Champaign, passed assistant surgeon U.S. Public Health Service Reserve. According to the Illinois Department of Public Health, this is an unprecedented action by the state to share with a local health office the services of a division chief.

Chicago

Billings Lecture—The Institute of Medicine of Chicago announces that Carl Voegtlin, Ph.D., chief of the National Cancer Institute, Bethesda, Md., will deliver the fifth Frank Billings Lecture of the Thomas Lewis Gilmer Foundation at the Palmer House, May 28. His subject will be "Chemistry of Carcinogenesis and Tumor Growth."

Mental Hygiene Meeting—Dr Davis Slight, professor of psychiatry, University of Chicago, was reelected president of the Illinois Society for Mental Hygiene at its thirty-fourth annual meeting in Chicago, March 15. William B. Brsile, lawyer, is secretary. Harold G. Webster, Detroit, executive secretary of the Michigan Society for Mental Hygiene, addressed the meeting on "Strategy and Tactics in Mental Hygiene."

INDIANA

Hospital Ward Named for Physician—A forty bed obstetric ward at the Indianapolis City Hospital was dedicated and named, March 23, in honor of Dr Henry F. Beckman, Indianapolis, who has been in charge of the obstetric service at the hospital for more than thirty years. A bronze plaque was unveiled in the ward by Dr Charles W. Myers, medical superintendent of the hospital, as a feature of the dedication to Dr Beckman. Another feature of the occasion was a talk by Sister Elizabeth Kennen.

MARYLAND

Annual Medical and Chirurgical Faculty Meeting—The annual meeting of the Medical and Chirurgical Faculty of the State of Maryland will be held in Baltimore, April 27-28. Dr. Charles R. Austrian, Baltimore, president of the faculty, will deliver the presidential address on "Plans for Medical Care." Dr. Frank L. Horsfall Jr., New York, will present the Trumble Lecture on "Primary Atypical Pneumonia." Included on the program will be the following Baltimore physicians:

Dr. Marcus M. Rivitch, Preparation and Uses of Frozen and Dried Plasma
Dr. Warfield M. Titor, Tetanus and Gas Infections
Dr. Otto C. Brantigan, Compression Treatment of Burns
Dr. James G. Arnold Jr., Management of Acute Head Injuries
Dr. Charles A. Reifschneider, Intra Abdominal Injuries
Dr. Warde B. Allen, Cardiac Problems in Aviation

One session will be devoted to "The Distribution and Redistribution of Physicians in the United States." Dr. Arthur M. Shipley, Baltimore, will be chairman of the discussion and speakers will be Dr. Harvey B. Stone, Baltimore, and Brig. Gen. George F. Lull, M. C., U. S. Army, Washington, D. C. Twenty-four subjects will be covered in the round table discussion at the Belvedere Hotel, April 28.

MASSACHUSETTS

The Cutter Lecture on Preventive Medicine—Dr. Lowell T. Coggeshall, professor of epidemiology, University of Michigan School of Public Health, Ann Arbor, Mich., will deliver the Cutter Lecture on preventive medicine, April 27, at Harvard Medical School on "Importance of Tropical Diseases in the Current and Post War Period."

Fiftieth Anniversary of Tufts Medical School—September has been tentatively selected as the month to mark the fiftieth anniversary of Tufts College Medical School, Boston. The nature of the celebration will be appropriate to the wartime exigencies and preoccupations of those concerned when the time approaches. A committee has been appointed to develop plans and arrangements for the observance.

MISSISSIPPI

Student Loan Fund—A gift of \$2,500, with a similar amount to be added in 1944, to the University of Mississippi School of Medicine, University, for the establishment of the G. D. Shands Memorial Loan Fund for medical students has been received from Paul Hill Saunders, Ph.D., and his wife of New Orleans and New York, newspapers reported March 14. The fund was presented in memory of the late Gov. Garvin D. Shands, Mrs. Saunders' father and for many years dean of the university school of law. It will be made available to worthy students who complete the two year course offered by the university and who need financial aid to finish their medical training at other schools.

NEVADA

Annual Registration Due May 1—All persons holding licenses to practice medicine in Nevada are required by law to pay annually to the treasurer of the Board of Medical Examiners, on or before May 1, a tax of \$2. Failure to do so operates to forfeit a licensee's right to practice medicine, and his license to practice can be reinstated thereafter only on payment of a \$10 penalty.

NEW YORK

Outbreak of Sore Throat—An outbreak of 56 cases of sore throat early in March in a village in Saratoga County has been traced to the consumption of raw milk. *Health News* reports that, although the epidemiologic investigation has not been completed, it is estimated that on the basis of the number of consumers of the suspected milk a total of 130 persons were affected. The illness was characterized by acute onset, severe sore throat with considerable purulent exudate, enlarged cervical glands and frequently, generalized symptoms including chills, fever and considerable prostration. The attack rate among persons drinking the incriminated milk was 36.4 per cent for those under 15 years of age and 44.1 per cent for those over 15 years. The health officer suspected an outbreak when 5 cases of sore throat, with onsets within a three day period, occurred in his practice. A house to house survey of a portion of the village showed that there were 31 cases among 79 consumers of milk from the implicated dairy and no cases among 55 consumers of milk from other dairies. Pasteurization of the suspected supply was instituted immediately, and no additional cases were reported with onsets occurring more than forty-eight hours after pasteurization was begun.

New York City

Symposium on the Premature Infant—The Zeta chapter of Phi Delta Epsilon fraternity at Long Island College of Medicine, Brooklyn, announces a symposium with Dr. Sam Z. Levine, professor of pediatrics, Cornell University Medical College, New York, speaking on "The Handicaps of the Premature Infant." The discussion will be carried out by Drs. Charles A. Weymuller and Murray B. Gordon, professor of pediatrics and professor of clinical pediatrics, respectively, Long Island College of Medicine. The symposium will be presented at Hoagland Hall, Brooklyn, April 20.

NORTH CAROLINA

Tuberculosis Meeting Canceled—At a recent meeting of the North Carolina Tuberculosis Association in Raleigh the executive committee voted to dispense with the usual annual meeting. Business matters will be settled at a meeting of the board of directors, the time to be announced later.

Venereal Disease Education Institute—Announcement is made of the recent establishment in Raleigh of the Venereal Disease Education Institute which is supervised by Mr. Capus M. Waynick, newspaper editor, High Point and by the state board of health, to disseminate educational material on venereal diseases. The institute is operated by the U. S. Public Health Service and the Zachary Smith Reynolds Foundation, which has been supporting public health work in North Carolina for many years.

OHIO

Use of Radio for Health Education—The Institute for Education by Radio sponsored by Ohio State University will devote a section meeting to "The Use of Radio for Health Education" at the Deshler-Wallick Hotel, Columbus, May 1, under the chairmanship of David Resnick, director of public relations, National Society for the Prevention of Blindness, New York. Speakers will include:

Sterling W. Fisher, assistant public service counselor and director of the Inter American University of the Air, National Broadcasting Company, New York. The Role of the Broadcasting Industry in Health Education.
Dr. William W. Bauer, director, Bureau of Health Education, American Medical Association, Chicago. When Doctors Broadcast.
Daniel C. McCarthy, director of public relations, National Tuberculosis Association, New York. Selling Health by Radio.
Thomas C. Stowell, assistant director, division of public health education, New York State Department of Health, Albany. N. Y. Health on the Air Comes of Age in New York.

The Institute's annual conference will be held from April 30 to May 3.

Vesalius Exhibit—In commemoration of the quartercentenary of the foundation of modern anatomy by Andreas Vesalius, an exhibit has been arranged in the Cleveland Medical Library. The exhibit was prepared by the staff of the Cleveland Branch of the Army Medical Library and the books are largely from its collections. Two important items from the collection of the Cleveland Medical Library, however, include a copy of the second edition of the *Fabrica* (1555), presented to the association in 1893 by Dr. Howard A. Kelly, who died in January 1943, and a copy of the first edition of the compendium of Geminus plagiarized from Vesalius in 1945. All the works of Vesalius are represented in the exhibit, though not in every case by first editions. Included in the exhibit are two copies of the *Geminus* compendium, London 1545; the first edition of *Fallopian's Observations*, Venice, 1561; a copy of the attack on Vesalius by his former teacher Jacques Dubois (1551, represented by 1635 reprint) and a copy of the rare Murr reprint (1790) of the *Christianismi restitutio* of Servetus (1553), for which he was burned at the stake in Calvin's Geneva and which contains the earliest account of the pulmonary circulation perhaps arrived at when he was fellow prosecutor of Vesalius at Paris about 1536.

TEXAS

Exhibit of Rare Medical Books—A special exhibit of rare medical books from the collections of Chauncey D. Leake, Ph.D., dean and vice president of the University of Texas Medical Branch, Galveston, and of the medical school library was held at the University of Texas Library, Austin. At the opening of the exhibit Dr. Leake spoke to premedical students and faculty members on "The Medical Books or Fine Printers" illustrating his remarks with particular emphasis on the *Fabrica* of Andreas Vesalius, first published in Basel four hundred years ago.

GENERAL

War-time Public Health Conference—The American Public Health Association will sponsor a three day public health conference in New York, October 12-14. The seventy-second annual business meeting of the association will be held in connection with the conference, which will be devoted exclusively to war-time emergency problems as they affect public health and the public health profession. New York City was selected because more than 40 per cent of the association's membership is concentrated in and immediately around it.

Report of Menninger Foundation—The first annual report of the Menninger Foundation, Topeka, Kan. covering the period April 1941 to July 1942, has been received. Work was carried out during the first year of operation on education and treatment of neurotic children, hypnosis, occupational therapy and psychoanalytic training and psychologic testing. At the recent annual meeting all the officers of the foundation were reelected including Drs. Karl A. Menninger, president and William C. Menninger, secretary. An executive assistant, Jean Lyle Menninger, has been added to the staff to aid the secretary during his absence with the armed forces.

Chemist Awarded Prize for Research in Milk—Earle O. Whittier, Chem. E. senior chemist of the bureau of dairy industry, U. S. Department of Agriculture, Washington, D. C. has been awarded the Borden Company Prize of \$1,000 for research in chemistry of milk. The prize, which was to be presented April 14 at a meeting of the society in Detroit, is given in recognition of researches in the chemistry of milk constituents. Dr. Whittier received his degree as a chemical engineer at the University of Maine, Orono in 1923. He had been a member of the teaching staff there from 1911 to 1915, when he went to Simmons College, Boston. From 1918 to 1921, when he joined the department of agriculture, he was research chemist at E. I. du Pont de Nemours and Company.

Advisory Committee of Nutrition Foundation—The Nutrition Foundation announces the following appointments to the food industries advisory committee: Franklin C. Bing, Ph.D., director, American Institute of Baking, Chicago; Edwin J. Cameron, Ph.D., director, Research Laboratories National Canners Association, Washington, D. C.; Lillian B. Stornis, nutrition research, Gerber Products Company, Fremont; Mich. Carl Nordgren, research chemist, Chr. Hensens Laboratories, Inc., Milwaukee; George C. Scott, M.S., director of research, Minnesota Valley Canning Company, Le Sueur; Louis E. Dietrich, director of production and research, P. Duff & Sons, Inc., Pittsburgh; Roland A. Morek, research department, R. B. Davis Company, Hoboken; N. J. Arthur Weber, process superintendent, National Sugar Refining Company, New York; and C. G. Harrel, director of research, Pillsbury Flour Mills Company, Minneapolis. The advisory committee serves as a liaison group between the foundation and the food industry.

Conference to Consider Additions to Pharmacopeia—A pharmacopoeial open conference, dealing with the forthcoming first U. S. P. XII bound supplement, will be held at the Hotel Pennsylvania, New York, April 23-24. The major subject for discussion Friday evening will be the U. S. P. XII requirement that multiple dose packages of parenteral solutions be limited in size to ten average doses. An all day program Saturday will cover about one hundred revisions and other alterations in monographs now official in the U. S. P. XII. Following the open conference and a consideration of suggestions and discussions the material will be printed as the first U. S. P. XII Bound Supplement. It was thought that this supplement would not be required for at least two years but demands by war interests and the increased revision tempo have required so many changes and additions that its immediate publication became necessary. It will be distributed without further charge to all purchasers of the U. S. P. XII who mail in the order coupon found inside the back cover of the U. S. P. XII.

Medical Service Plans Meet in Chicago—At a meeting of representatives of the various medical service plans, held in Chicago on February 14, it was agreed that an annual conference of representatives of such plans be held each year and that such a group form a council with president and secretary-treasurer. Dr. James C. McCann of Worcester, Mass., was elected president. Dr. Frank L. Feerabnd of Kansas City, Mo., was elected secretary-treasurer. It was voted that a committee be appointed to act as a group to provide cooperation between the American Medical Association, the Canadian Medical Association and the new Medical Service Plans Council. The committee appointed consists of Drs. Chauncey L. Palmer

of Pittsburgh, chairman, Jason A. Hinrich of Toronto and Robert L. Novy of Detroit. Mr. Jack Laux, Detroit, of the Michigan plan was appointed research director. It was also agreed that a meeting of this group be held at the time of the meeting of the House of Delegates of the American Medical Association in Chicago. Kansas City, Mo., was selected as the national headquarters for the council, and an annual contribution of \$25 was volunteered by each organization to pay the expenses of the function.

HAWAII

Island Health Activities—William L. Zink, assistant surgeon, U. S. Public Health Service Reserve has been assigned to operate the new mobile x-ray unit of the Territory of Hawaii health board.—Dr. Alfred S. Hartwell, Honolulu, has recently been named medical director for Queen's Hospital. A new building has been constructed at the hospital to house the Honolulu Blood Bank. Funds were provided by the Office of Civilian Defense.—The Hawaii Territorial Society for Mental Hygiene was recently organized under the auspices of the Psychiatric Committee of the Hawaii Territorial Medical Association.—The name of Japanese Charity Hospital, Honolulu, has been changed to Kurekuni Hospital.—Major Charles L. Wilbur Jr., M. C. U. S. Army, has been appointed health officer of Maui County with headquarters in Wailuku.

CANADA

First Social Hygiene Day—On February 3 the first Canadian Social Hygiene Day was observed under the auspices of the Health League of Canada according to the *Canadian Journal of Public Health*.

Memorial to Physician at Queen's University—Graduates of the Queen's University Faculty of Medicine, Kingston, Ont., have donated a number of old medical books to form the nucleus of a medical history collection to be used as a memorial to Dr. Thomas Gibson who at the time of his death was professor of the history of medicine at the university.

LATIN AMERICA

Pension Fund for Physicians—President Batista of Cuba signed a bill on February 20 setting up a pension fund for physicians. The *New York Times* reported that the legislation creates a tax on all pharmaceutical products sold in Cuba and on the fees paid by members of cooperative health associations. Physicians will contribute 3 per cent of their earnings.

FOREIGN

Chadwick Lectures—The series of Chadwick Public Lectures, arranged by the Chadwick Trust, Abbey House, Westminster, appears in the *British Medical Journal* as follows: M. Greenwood, February 23, on 'Social and Industrial Environment and Disease'; Dr. R. Cruickshank, March 16, 'Some Postwar Problems in the Control of Infectious Diseases'; Mr. T. Sharp, April 6, 'Town Planning and Public Health'; Dr. C. F. White, May 11, 'Health Problems in Rebuilt London'; and Mr. I. J. Clutton-Brown, June 17, 'Plants Causing Irritation'.

Government Services

Results of Tuberculosis Surveys

Seventy-seven war industries in eleven different states were surveyed by the eight 35 mm. photo-fluorographic units operating in industry prior to February 1, according to the Office of Tuberculosis Control of the United States Public Health Service. A total of 194,896 individuals were x-rayed. Tabulations on results of the x-ray examination are available for 125,190 people. Of these, 1,631 or 1.3 per cent were found to have significant pulmonary tuberculosis. The distribution of the positive cases by stage of the disease was as follows: 874 or 53.6 per cent minimal, 707, or 43.3 per cent moderately advanced, and 50, or 3.1 per cent far advanced. In the District of Columbia 28,098 government workers have been x-rayed. Exactly 300 cases (1.1 per cent) of pulmonary tuberculosis have been discovered. Of these 182 (60.7 per cent) were minimal, 106 (35.3 per cent) moderately advanced and 12 (4.0 per cent) were far advanced. In addition 1,300 workers at the National Institute of Health have been x-rayed. Among these, 15 cases of tuberculosis were found, 9 minimal and 6 moderately advanced.

Foreign Letters

Feb 27 1943

Reaction of Medical Association to the Beveridge Scheme

In a previous letter to *THE JOURNAL* (January 9 p 142) the Beveridge Report, which is a comprehensive scheme of social insurance with freedom from want as its goal was described. It is of profound importance to the medical profession for it proposes that the state should provide medical care, domiciliary as well as hospital for all. This might mean the extinction, or something near that, of private practice and conversion of the medical profession into state officials. Various committees of the British Medical Association have been studying the report and their recommendations have been brought before the council, which has framed a motion for transmission to the representative body of the association. This motion recommends that if Parliament accepts the report as a whole including a scheme for comprehensive health and rehabilitation services for the prevention and cure of disease and restoration of capacity to work available to all members of the community, the association would be willing to cooperate in the preparation of such a scheme, provided (1) that the character terms and conditions of the medical service are determined by negotiation and agreement with the medical profession, (2) that the members of the community who decide not to avail themselves in part or in whole of the benefits of the service open to them should not be precluded from obtaining the medical services they desire from doctors within the scheme paying for such services privately, with the necessary safeguards to prevent abuse. This recommendation will be considered by a special meeting of the representative body and of the panel conference and by a joint meeting of the two at the end of March. In the interval the divisions of the association will consider the council's recommendation.

The decision of the council is evidently due to two considerations. The medical profession could not refuse cooperation with the Beveridge scheme of social reform from which so much is hoped, if it is adopted by Parliament. The majority of the profession is opposed to the total abolition of private practice and the conversion of physicians into government officials. To prevent this, the second provision of the council's recommendation has been framed.

Scheme for the Prophylaxis of Tetanus

The prophylactic scheme against tetanus differs in the British and American armies. The American army, like the Canadian, relies entirely on active immunization while the British uses also passive immunization. The soldier gets a dose of toxoid on joining, a second dose about six weeks later and a further dose every twelve months. According to the *Army Medical Bulletin* (November 1942) this procedure sets up a 'shadow factory' for antitoxin and keeps it in commission but it does not maintain the circulating antitoxin at a constant high level. When tetanus organisms enter the body there may be a danger period of several days before the shadow factory begins to produce antitoxin in quantity and it is necessary to protect the patient during this danger period by giving him antitoxin at least 3000 units as soon as possible after he is wounded. This routine passive immunization has the advantage that it covers any men who may have refused or escaped active immunization. But such men will require two extra doses of 3000 units at weekly intervals to make them safe.

In the American army active immunization is compulsory and is carried further. Not only does the recruit receive three spaced injections of toxoid but on entering a theater of war he has a fourth dose and renewal doses every four months thereafter. The American authorities believe that these inoculations maintain so high a level of circulating antitoxin that passive immunization after wounding is unnecessary. Instead of antitoxin American soldiers are given a final 'boosting' dose of toxoid.

As in warfare American wounded may be brought to British hospitals and vice versa, the following arrangement has been made. The American authorities have asked that their soldiers should receive a boosting dose of toxoid instead of the British dose of antitoxin and the Canadian authorities have made the same request. This will be done whenever possible. On the other hand the American authorities have agreed that British wounded in American hospitals shall receive prophylactic antitoxin.

Medical Research in the Army

The medical corps of the British army has a long and distinguished record of medical research. To it is due much of our knowledge of disease in the British colonies. It now has medical research sections at home and abroad whose task is to bring to light urgent problems and advise on their solution. The *Army Medical Bulletin* for November 1942 points out that the health of a mechanized army is a matter of infinite detail and roving research cannot cover the whole ground. Often the person most likely to know what is needed is the junior medical officer who lives among the troops. He is in the best position to detect avoidable causes of sickness, disability and overstrain.

In industrial medicine the emphasis shifted a few years ago from the cure to the prevention of disease and is now shifting toward the maintenance of health in each particular occupation. The same is happening in the army. It is for the medical officer to notice the cramped position, the visual fatigue, the failure of vitality, the cold hands, the diarrhea or the incipient heat stroke. Medical officers who have noted specific problems of bodily or mental efficiency susceptible of solution by themselves or others are asked to forward them to the Director of Medical Research to the Army whose task is to coordinate investigations and initiate inquiries.

The role of the medical services as experts in all that concerns the human factor in warfare has been formally recognized by the military authorities. For some time the army council has had a scientific adviser. Sir Charles Darwin, FRS, but he and his staff are concerned only with weapons, equipment and ways of making war. A need was felt for a complementary adviser on the biologic side. The director of medical research, Brigadier F A E Crew, FRS, will henceforth fulfil this function on the same level as the scientific adviser. In doing so he will require all possible information on great matters and on small from the periphery and especially from the field.

Sir William Arbuthnot Lane

Sir William Arbuthnot Lane has died in his eighty-seventh year. He was trained at Guy's Hospital, passing the examination for fellowship of the Royal College of Surgeons when he was only 26. His first appointment was demonstrator of anatomy at Guy's, to be followed by surgeon to the Hospital for Sick Children, Great Ormond Street, and assistant surgeon to Guy's. He published a long series of papers on the most diverse subjects marked by daring originality. His first surgical innovation was excision of a piece of rib in treating an empyema; his next to operate for cleft palate early in life. He introduced the screwing or plating of fractures of long bones when accurate apposition could not otherwise be obtained. He published *The Operative Treatment of Fractures*. His skill in the operative

treatment of comminuted fractures of the femur was amazing. He was much interested in the disorders of the skeleton, which he traced to pressure changes induced by the patient's occupation. He pointed out that these changes revealed the work done during life. Thus the skeleton of the cobbler or the washerwoman was characteristic, and the effect of the corset on the abdominal viscera affected the mechanics of the foot. He saw in the skeleton the crystallization of lines of force. He boasted that he could tell in the dissecting room the occupation followed during life by a manual worker. At the beginning of the century he began to teach that much ill health was due to stagnation in the large intestine (intestinal stasis). He denounced the usual view that one daily evacuation was sufficient and said that if man reverted to the habit of three motions daily many diseases, including cancer, would disappear. He described a kink due to formation of thin tags of peritoneum which anchored the iliac colon. These he attributed to excessive straining caused by fecal accumulation in the colon. He treated some cases by excision of the colon. A great fighter, his failure to convince the profession only spurred him to increased polemics in the form of many papers, culminating in his book "The Operative Treatment of Chronic Constipation." He felt so strongly on the subject that he resorted to the lay press and ended by resigning his membership in the British Medical Association and founding the New Health Society to promote his hygienic gospel. Thus a great surgeon ended a long life as a medical crank.

BUENOS AIRES

(From Our Regular Correspondent)

Jan. 12, 1943

The Faculty of Medicine of Rosario

The Faculty of Medicine of Rosario, founded in 1920, is formed now by the schools of medicine, odontology, pharmacy, biochemistry, obstetrics, legal medicine and pediatrics and is one of the various faculties of the University of the Litoral. The number of students has grown from 173 in 1920 to 3,600 at present. Up to 1940 a total number of about 2,800 professionals, including more than 1,000 physicians, have graduated from the faculty. The development of scientific research work has been hindered to some extent because of the shortage of money and of research material. Only a group of teachers among those who work on a full time program are devoted to both teaching and research. Several medical societies of the various medical specialties have been founded by the members of the various departments of the faculty, scientific journals have been established and a large assembly hall founded. The hospital Nacional Centenario with 650 beds is the main focal point of the faculty. The number of hospitalized and ambulatory patients who have consultation and medical care annually is 10,000 and 100,000 patients respectively. There are also clinics of all the specialties, an institute of psychiatry, a hospital for the insane and a school for children with retarded mentality. There are also a central library of the faculty and a classic library of the chair of history of medicine.

Public Health in Paraguay

General Don Higinio Moringo M., the president of Paraguay, in his presidential message, recently delivered, spoke on the constant progress of the national organization of public health in the country. The problems of hygiene and public health are given proper attention all through the country, even in the remote villages and rural places. An antimalarial crusade was recently successfully completed notwithstanding the fact that malaria had rapidly flared up all through the country in violent form. New hospitals are in construction, and those which are

already functioning are modernized. Industrial hygiene is also improved. Laws have been given by which workers and their families have free medical care and drugs. The antituberculosis crusade is directed by a committee of specialized experts. New posts for free distribution of milk for infants and centers for therapy of venereal and syphilitic diseases have been opened to the public. The organization of a national department of nutrition and studies for establishment of obligatory social insurance are in progress.

Malignant Lymphogranulomatosis

Dr. A. A. Ferraris recently reported clinical studies on 15 children who suffered from malignant lymphogranulomatosis in the Hospital of Niños of Córdoba. The patients between the ages of 5 and 12 years were all boys except 1. The disease began with a ganglionic tumor of slow development in the neck in 12 cases. In 3 cases the disease began with acute abdominal symptoms which suggested an emergency operation. There was splenomegaly in 70 per cent of the cases and moderate hepatomegaly in 60 per cent of the cases. The Mantoux intradermal test was carried on in all cases in concentrations of 1:10; positive results were observed in only 2 patients. The same proportion of positivity is obtained in normal children of the city. Two patients had pruritus. Twelve had moderate fever and 3 had no fever. There was a moderate leukocytosis with neutrophilia and without eosinophilia in all cases, notwithstanding that the ganglions showed a large number of polymorphonuclear eosinophils on microscopic study. There was leukopenia with figures varying between 4,000 and 2,000 leukocytes in 3 cases. There were also changes in the erythrocytes of the type of hypochromic anemia. In all cases the histopathologic study of the enlarged ganglions gave results for a proper diagnosis of the disease and the Sternberg cells were found in the specific granuloma tissue. The Sternberg cells were scanty in some cases and abundant in some whereas the polymorphonuclear eosinophils were abundant in all cases. Giant cells similar to those of Langhans were observed in the blood of 2 patients with and without positive results of the Mantoux test respectively. The microscopic study of material obtained during a necropsy showed the ordinary involvement of the various organs by the disease. In the bone marrow of the sternum and of other bones the hemopoietic tissue was replaced by granuloma tissue only partially (in foci) and late in course of the disease. In all cases death occurred within one to five years notwithstanding that roentgen therapy was administered.

Erythroblastic Anemia

Dr. M. Acuña, president of the Society of the Instituto de Pediatría y Puericultura of the Hospital de Clínicas de Buenos Aires, in a recent lecture before this society said that erythroblastic anemia of Cooley's type in infants (also called erythroblastic anemia of either von Jaksch's or Luzet's type) should be differentiated by any of these names from any other forms of anemia in infants. The speaker reported two series, one of 4 and another of 7 cases. The clinical course consisted in early appearance of progressive anemia, hepatomegaly, splenomegaly, presence of erythroblasts in the blood, osteoporosis of the skeletal bones, congenital familial ethnic character and lack of any disease which could have been considered as cause of anemia. All the patients formerly lived in the Mediterranean area. There were several patients in the family of all patients but there were also normal children. Even in couples of twins one was ill and the other was normal. The disease appeared in the course of the first six months of life of the patients and was of the typical form when the infants reached 1 year of age. The cause was unknown in all cases. The 4 patients in the first series and 6 patients of the second series died. The patient in the second group who is still living is in a grave condition.

Deaths

Arnold Carl Klebs, Nyon, Switzerland, medical humanist and student of the scientific and medical literature of the 15th century, died at his villa Les Terrasses, Nyon March 6 aged 72.

Dr Klebs was born in Berne, Switzerland, March 17, 1870. He was a son of Dr Edwin Klebs who, with Loeffler, had discovered the diphtheria bacillus. After his graduation in 1895 at the Universität Basel Medizinische Fakultät, Dr Klebs was for a time assistant in the polyclinic at the Basel University and pathologic instructor at the University of Zurich. In 1896 he came to the United States and devoted himself to the study of tuberculosis. For a time he was head of the tuberculosis sanatorium at Citronelle, Ala., later going to Chicago, where his father had been professor of pathology at Rush Medical College since 1896. In 1904 he became a citizen of the United States. During his years in Chicago he served as consulting physician to the Cook County Institutions and as director of the Chicago Tuberculosis Institute. Dr Klebs returned to Switzerland in 1909, from 1915 to 1918, Washington, D. C., and 1918 to 1919, New York, where he returned again for one year in 1926. Dr Klebs was vice president of the section on preventive diseases of the International Congress on Hygiene, Washington, in 1912. At one time he had held membership in the American Chemical and Climatological Association, the National Tuberculosis Association and numerous foreign and scientific societies. When Dr Klebs took up permanent residence in Switzerland he dropped his membership in the Illinois State Medical Society and fellowship in the American Medical Association.

Following the first war Dr Klebs came to the United States once each year until 1930, when poor health forced him to abandon his annual expeditions. His last trip was in April 1939, when he came secretly to surprise the late Dr Harvey Cushing on his seventieth birthday, which the Harvey Cushing Society was celebrating in New Haven, Conn.

Dr Klebs had written extensively on medical and historical subjects. In 1909 he was the editor of the American Treatise on Tuberculosis, History of Variolation, 1914, Leonardo da Vinci Studies, 1916, Tuberculosis and Military Organization, 1917, Bibliography of Medical Incunabula, 1917, 1918, Early Herbals (Lugano), 1925, and Incunabula Scientifica et Medica 1938. Dr Klebs was a close friend of Osler, Welch and Cushing and it was because of his long friendship with Cushing that he became affiliated with Yale and the Yale Medical Library.

William Hoffman Gardner Logan ☉ Chicago, Chicago College of Dental Surgery, 1896, American College of Medicine and Surgery, Medical Department of Valparaiso University, 1903, dean of the faculty and professor of plastic and oral surgery at the Chicago College of Dental Surgery Dental School of Loyola University, past president of the National Dental Association, Illinois State Dental Society, Chicago Dental Society, the seventh International Dental Congress and the American Association of Dental Schools, formerly vice president and president of the International Dental Federation, specialist certified by the American Board of Plastic Surgery, member of the American Association of Oral and Plastic Surgeons, fellow and a member of the board of governors of the American College of Surgeons, during World War I served as chief of the dental division of the Surgeon General's Office in Washington, D. C., member of the general medical board of the Council of National Defense, secretary from 1929 to 1933 and member of the board of governors from 1933 to 1941 of the Gorgas Memorial Institute of Tropical and Preventive Medicine, received the honorary degrees of doctor of laws from Loyola University in 1926 and the National University of Ireland, Dublin, in 1940, master of science from the University of Michigan, Ann Arbor, in 1930, was awarded the William Jarvie Fellowship Medal of the Dental Society of the State of New York, senior attending surgeon in oral surgery at the Michael Reese Hospital, on the staffs of the Cook County and St. Joseph's hospitals, aged 70, died, April 6, of coronary thrombosis.

James Bassett McElroy ☉ Memphis, Tenn., College of Physicians and Surgeons, Baltimore, 1893, professor of medicine, for many years chief of the division of medicine and at one time acting dean, member of the board of trustees and chairman of the faculty of the University of Tennessee College of Medicine, formerly professor of pathology at the Memphis Hospital Medical College, where in 1905 he served as chief of the dispensary and as lecturer in physical diagnosis, specialist

certified by the American Board of Internal Medicine secretary of the Section on Practice of Medicine of the American Medical Association, 1902-1903, past president of the Tennessee State Medical Association and the Memphis and Shelby County Medical Society, member of the Southern Medical Association and the American Society of Tropical Medicine, fellow and ex-governor of the American College of Physicians, chief of staff and physician in chief of the medical division of the Memphis General Hospital now known as the John Gaston Hospital, on the staff of the Baptist Memorial Hospital, in 1934, at the commencement exercises of the University of Tennessee College of Medicine, his portrait was presented to the university by members of the faculty and the alumni, aged 76, died, March 24.

William Birket Arnold, St. Albans, Vt., Bellevue Hospital Medical College, New York, 1888, member of the Vermont State Medical Society, served as city health officer and city physician for many years, on the staff of St. Albans Hospital, aged 83, died, February 27, of heart disease.

Walter Milo Barnum, Kent, Conn., College of Physicians and Surgeons, New York, 1883, also a druggist, aged 83, died, February 19, of coronary occlusion.

Robert Lee Beaumont, Kansas City, Mo., Beaumont Hospital Medical College, St. Louis, 1889, aged 80, died, January 20, in the Armour Memorial Home of chronic myocarditis.

Sylvester Robert Best, Gary, Ind., Ohio Medical University, Columbus, 1898, member of the Indiana State Medical Association, aged 70, died, February 13, in St. Mary's Mercy Hospital of coronary occlusion.

James Emmett Blagg, Philadelphia, Eclectic Medical Institute, Cincinnati, 1905, member of the Medical Society of the State of Pennsylvania, aged 67, died recently in the Jewish Hospital of coronary thrombosis.

John Willet Bruner ☉ Bloomsburg, Pa., Jefferson Medical College of Philadelphia, 1890, fellow of the American College of Surgeons, aged 77, instrumental in the founding, surgeon in chief on the staff and member of the board of directors of the Bloomsburg Hospital, where he died, February 10, of uremia.

Cornelius E. Cain, Whitley City, Ky., Barnes Medical College, St. Louis, 1901, a director of the Bank of McCreary County, aged 70, died, February 6, in Washington, D. C., of brain tumor.

Hanford Carvell, Gloucester, Mass., Baltimore Medical College, 1910, member of the Massachusetts Medical Society, aged 67, member of the senior staff of the Addison Gilbert Hospital, where he died, February 15, of virus pneumonia and myocarditis.

William Cogswell Clarke, Cornwall Bridge, Conn., Columbia University College of Physicians and Surgeons, New York, 1899, member of the Connecticut State Medical Society, served as professor of experimental surgery at his alma mater and surgical pathologist to the Presbyterian Hospital, New York, member of the consulting staff of the Sharon (Conn.) Hospital, aged 71, died suddenly, February 14, of coronary occlusion.

William Henry Conner, Fort Wayne, Ind., Howard University College of Medicine, Washington, D. C., 1894, aged 81, died, February 19, of influenza and myocarditis.

Augustus Ernest Cordes ☉ Brooklyn, Albany (N. Y.) Medical College, 1899, served during World War I, aged 70, died, February 14, of coronary thrombosis.

Edward F. W. Crawford, La Porte, Ind., Detroit College of Medicine, 1894, member of the Indiana State Medical Association, aged 73, on the staff of the Holy Family Hospital, where he died, February 4, of myocarditis.

Oren Louis Cuddy, Lincoln, Mo., Barnes Medical College, St. Louis, 1903, member of the Missouri State Medical Association, past president of the Benton County Medical Society, for thirty years local and dispensing surgeon for the Missouri Pacific Railway Company, for ten years served as city physician served on the advisory board and as a member of the medical reserve corps during World War I, aged 67, on the staff of the Bothwell Memorial Hospital, Sedalia, where he died, February 19, of pneumonia and coronary embolism.

Charles Louis Davis, Batavia, N. Y., University of Buffalo School of Medicine, 1907, member of the Medical Society of the State of New York, served on the staffs of the Batavia and St. Jerome hospitals, New York State School for the Blind and the Genesee County Home-Infirmiry, aged 60, died, February 19, of carcinoma of the rectum.

Francis Asbury De Mand * Oklahoma City University of Oklahoma School of Medicine, Oklahoma City, 1917 served in France during World War I, associate in obstetrics at his alma mater, aged 50, on the staffs of St. Anthony Hospital and the University Hospital, where he died, February 11, of rheumatic heart disease

Albert Edward Doe, Chicago Chicago Medical School, 1921, a member of the medical department of the Chicago Rapid Transit Company, aged 61, died February 13, in the Albert Merritt Billings Hospital of pneumonia following an operation

Joseph Alexander Driscoll, Brooklyn Long Island College Hospital, Brooklyn, 1908, formerly physician to the District Attorneys office, served on the staffs of St. Catherine's and the Caledonian hospitals, aged 56, died, February 18, of cerebral hemorrhage and uremia

Joseph Baylis Earle, Greenville S. C. University of Virginia Department of Medicine Charlottesville 1886 member of the South Carolina Medical Association formerly medical director of the Pioneer Life Insurance Company and the Liberty Life Insurance Company, aged 80 died February 10 of heart disease

Lewis H. Edwards, Monroeville Ind. Fort Wayne College of Medicine 1883 aged 82, died February 12 in the Adams County Memorial Hospital, Decatur, of chronic myocarditis and pneumonia

Adolf A. Eisenheimer, Akron, Ohio Julius Maximilians Universitat Medizinische Fakultät, Würzburg Bavaria, Germany, 1912, aged 56, died, February 15 of coronary occlusion

Jacob Nathaniel Feinberg * Long Island City, N. Y., University and Bellevue Hospital Medical College New York, 1914, on the staff of St. John's Long Island City Hospital vice president and on the staff of the Boulevard Hospital where he died, February 10, of coronary thrombosis, aged 53

Attilio H. Giannini, Los Angeles University of California Medical Department San Francisco 1896 for many years a banker and motion picture executive, aged 68 died February 7 of heart disease while attending a meeting of the board of trustees of Loyola University

Earl P. Gray, Wilkensburg, Pa. Western Pennsylvania Medical College, Pittsburgh 1897, aged 73, died, February 24 of chronic nephritis and cirrhosis of the liver

Lesser Bernhardt Groeschel * Mount Vernon, N. Y., Columbia University College of Physicians and Surgeons, New York, 1906, specialist certified by the American Board of Radiology, Inc., member of the American Roentgen Ray Society and the American College of Radiology, roentgenologist at the Northern Westchester Hospital Mount Kisco St. Joseph's and the Professional hospitals Yonkers, and the Seton Hospital, New York, aged 56 died, February 23 in Scarsdale of coronary thrombosis

Elmer Garrison Harris, Los Angeles National University of Arts and Sciences Medical Department, St. Louis, 1918 served in the medical corps of the U. S. Army during World War I on the staff of the Presbyterian Hospital-Olinsted Memorial, aged 50 died February 14, in the Veterans Administration Facility, West Los Angeles of spinal sclerosis

George Frey Hermann Sr., Cincinnati Cincinnati College of Medicine and Surgery, 1896, aged 72, died, February 20 in the Bethesda Hospital of coronary disease

Charles Clinton Hoagland, Berkeley, Calif. Northwestern University Medical School Chicago, 1906 served on the staff of the Ernest V. Cowell Memorial Hospital, University of California, aged 63, died, February 10 of coronary occlusion

Alvah Alexander Howell, New Lebanon Ohio Starling Ohio Medical College Columbus, 1911, aged 65, died February 15, in the Miami Valley Hospital, Dayton, of pulmonary tuberculosis

John Preston Huff, Cartersville Ill. St. Louis College of Physicians and Surgeons, 1909, aged 62 died, February 25, of cerebral hemorrhage

Sergius M. Ingermar, New York Universitat Bern Medizinische Fakultät Switzerland, 1889 member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Otolaryngology, past president of the Russian Medical Society, aged 74, consultant in ophthalmology at the Beth David Hospital, where he died, February 18 of cerebral hemorrhage

George Boerstler Kistler, Newcomerstown, Ohio, Columbus Medical College, 1892, member of the Ohio State Medical Association, past president of the Tuscarawas County Medical Society, aged 76 was found dead in bed February 15

Albert Joseph Lawler * Niagara Falls N. Y., Niagara University Medical Department, Buffalo, 1898 fellow of the American College of Surgeons on the staff of St. Mary's Hospital, aged 65, died, February 16 of burns received when his clothes ignited while he was smoking

James M. Lemons, Pine Bluff, Ark. Memphis (Tenn.) Hospital Medical College, 1893, member and past president of the Arkansas Medical Society and the Jefferson County Medical Society, aged 80, died, February 3, of arteriosclerosis and chronic nephritis

Clarence M. Lentz, Albemarle, N. C. North Carolina Medical College, Charlotte, 1909, past president and secretary of the Stanly County Medical Society, served as county coroner, on the staff of the Yicklin Hospital, aged 57, died, February 13, of coronary thrombosis

Edgar Miller Long, Hamilton, N. C. University of Maryland School of Medicine, Baltimore, 1909, aged 56, died February 24 in the Park View Hospital, Rocky Mount of adrenal insufficiency

Emil Lustig, St. Petersburg, Fla., University of the City of New York Medical Department, 1883, member of the Florida Medical Association, also a pharmacist, medical examiner for the Selective Service Board in Buffalo during World War I, served on the staff of the Mound Park Hospital, aged 86, died, February 23, of heart disease

George Lyford, Cincinnati University of Cincinnati College of Medicine, 1925, member of the Ohio State Medical Association, on the staffs of the Cincinnati General and the Christian R. Holmes hospitals, medical director of the Union Bethel Clinic, aged 44, died, February 15, in the Christ Hospital of pneumonia and myocarditis

John Current McIntire, St. Louis, University of Louisville (Ky.) Medical Department, 1898 member of the Missouri State Medical Association, aged 66 on the staff of the Christian Hospital, where he died, February 16, of myocarditis

Sterling Price Martin, Blytheville, Ark., Barnes Medical College, St. Louis, 1903, served as city health officer, aged 70 died, February 1, in the Walls Hospital of angina pectoris

Americus Vespucius Menefee, Covington Ky., Louisville (Ky.) Medical College, 1892, member of the Kentucky State Medical Association served during World War I, aged 71, on the staff of St. Elizabeth Hospital, where he died February 17, of lobar pneumonia

Henry Taylor Miller * Washington, D. C., University College of Medicine, Richmond, Va., 1905, aged 61, staff surgeon at the Episcopal Eye Ear and Throat Hospital and the Doctors Hospital, where he died, February 7, following an operation for prostatic hypertrophy, paralytic ileus and heart disease

Alney Neal Minear, Inglewood, Calif. Medico Chirurgical College of Kansas City, Mo., 1905, member of the Utah State Medical Association, for many years practiced in Salt Lake City, aged 74, died January 11, in a hospital at Los Angeles of nephritis

Brutus Caesar Moore, Albemarle, N. C., Jefferson Medical College of Philadelphia, 1886, aged 86 died, February 22, of coronary thrombosis

Julia Mary Lombard Moriarty, Newton, Mass. Boston University School of Medicine, 1895, aged 70, died, February 16 in the Massachusetts General Hospital, Baker Memorial Boston, of hemorrhage and duodenal ulcer

Ralph Luther Morse * Norwalk, Ohio, University of Michigan Department of Medicine and Surgery, Ann Arbor 1902 on the staff of the Norwalk Memorial Hospital, aged 68 died February 21, of influenza and heart disease

Charles Borromeo O'Rourke, East Providence, R. I. Baltimore Medical College, 1907 member of the Rhode Island Medical Society, served during World War I medical examiner for East Providence for many years head of the medical examining board of the local draft board, on the staff of St. Joseph's Hospital formerly chairman of the East Providence branch of the Providence Chapter of the American Red Cross, aged 58 died February 13, in Providence of acute myocarditis

Milton Jay Parke, Lakewood Ohio, Western Reserve University Medical Department, Cleveland 1890 formerly on the staffs of St. Johns and St. Vincent Charity hospitals Cleveland, aged 79 died, February 9, of coronary sclerosis

James Fred Pfahler, Berwick, Pa. University of Pennsylvania Department of Medicine, Philadelphia, 1901 member of the Medical Society of the State of Pennsylvania served on the Berwick Hospital on the board of health and school board, aged 65, died suddenly, February 8 of coronary thrombosis

Don Pierce, Wyandoch, Mo., Barnes Medical College, St. Louis, 1901 member of the Missouri State Medical Association, aged 68, died recently of pneumonia and arthritis

John Hunter Pope, Tyler, Texas, Tulane University of Louisiana School of Medicine, New Orleans, 1918 served during World War I, member of the staff of the Mother Frances Hospital, aged 48, died, February 12, of a gunshot wound received while he was cleaning a pistol

Katherine Porter, Palo Alto, Calif., Johns Hopkins University School of Medicine, Baltimore, 1898, aged 72 died recently of cerebral hemorrhage

George William Purefoy, Asheville, N. C., Jefferson Medical College of Philadelphia, 1876, at one time a member of the county board of health, formerly on the staff of the Asheville-Biltmore Sanitarium, Biltmore, aged 92 died, February 23, of arteriosclerosis

Paul Emil Rauschenbach, Paterson, N. J., University of Virginia Department of Medicine, Charlottesville, 1904, member of the Medical Society of New Jersey, formerly served as city physician, aged 70, for many years served as director of the orthopedic clinic at the Paterson General Hospital, where he died, February 23, of embolism, heart disease and pneumonia

James Denny Reed, Contra Costa, Calif., Bellevue Hospital Medical College, New York, 1883, formerly served on the school board, as president of the Chamber of Commerce and as bank president, aged 84 died January 29, in the Contra Costa Hospital of pneumonia

Francis Gurney Reese & Condersport Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1895 served as president of the Potter County Medical Society and also as a member of its board of censors, formerly health officer, aged 72, died recently of carcinoma of the pancreas

John Franklin Reynolds, Mount Sterling, Ky., Hospital College of Medicine Louisville, 1890, died, February 10 of myocarditis, arteriosclerosis and gangrene of the right foot

William Bernard Riley, Lawrence, Mass., Harvard Medical School Boston 1911 served as city bacteriologist examiner for the Selective Service Board number 80 and examiner for the federal industrial accident board aged 58 died February 12, in the Lawrence General Hospital of cerebral hemorrhage

Francis Emerson Rosenberger & Oklahoma City, Beaumont Hospital Medical College, St. Louis, 1901, member of the Oklahoma County Sanitary Board, served on the medical advisory board during World War I aged 68, died, February 8, in the Polyclinic Hospital of heart disease

Jacob Coby Rosenbluth, New York, College of Physicians and Surgeons, New York, 1892, member of the Medical Society of the State of New York, aged 71 died February 21, of carcinoma

Abram S. Samuels & Baltimore, College of Physicians and Surgeons, Baltimore, 1898, also a pharmacist, clinical professor of gynecology at the University of Maryland School of Medicine and College of Physicians and Surgeons, member of the Society of American Bacteriologists, fellow of the American College of Surgeons, served on the staffs of the Mercy and Sinai hospitals, aged 66 died, February 7, of coronary thrombosis

Howard William Schaffer & Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1921, diplomate of the National Board of Medical Examiners, aged 46, on the staffs of the Memorial Hospital, Germantown Hospital and the Philadelphia General Hospital, where he died, February 11 of carcinoma of the bladder

Walter Jordan Sener, Media, Pa., Temple University School of Medicine, Philadelphia, 1911 member of the Medical Society of the State of Pennsylvania and of the American Academy of Ophthalmology and Otolaryngology aged 66 died recently of coronary occlusion

Harriet Belle Henry Short, Riverside, Calif., Northwestern University Woman's Medical School, Chicago, 1899, aged 71, died, January 31, of myocarditis

Percy Clinton Snowden, Peekskill, N. Y., University of Vermont College of Medicine, Burlington, 1893, member of the Medical Society of the State of New York, formerly on the staff of the Peekskill Hospital, aged 74 died, February 7, in the University Hospital, Coral Gables, Fla., of pneumonia

George Omar Speirs & Spearville, Kan., Rush Medical College, Chicago, 1900, fellow of the American College of Surgeons, formerly secretary of the Ford County Medical Society, councilor of the Twelfth District of the State Medical

Society, formerly mayor of Ellinwood, served on the city council and as mayor of Spearville for several terms, recently an examiner for the Hodgeman County draft board on the staffs of St. Anthony's Hospital, Dodge City, and the Perkins Hospital, aged 67 died, January 28

James Wesley Stack, Crumpton, Md., University of Maryland School of Medicine, Baltimore 1893, past president of the Queen Annes County Medical Society served as magistrate at Crumpton for many years, judge of the Queen Annes County Orphans Court from 1934 to 1938, aged 75, died, January 31

Joseph Francis Xavier Stack, Hoboken, N. J., Bellevue Hospital Medical College, New York, 1896, health commissioner of Hoboken for thirty-three years, aged 71, on the staff of St. Mary's Hospital where he died, February 17, of bronchopneumonia and cerebral hemorrhage

Earl Minor Stewart, Eagle, Neb., College of Physicians and Surgeons, Baltimore 1900, at one time practiced in Imperial, where he had for sixteen years been a member of the Chase County High School Board a county coroner, vice president of the Farmers and Merchants Bank and chairman of the Chase County Red Cross, aged 71 died, February 14 in Lincoln of terminal hypostasis due to cerebral arteriosclerosis

Edward von Toll, Pasadena, Calif., St. Louis College of Physicians and Surgeons, 1905, aged 75, died recently of hypostatic pneumonia

Otto Theodore Walser, St. Louis, Marion-Sims Beaumont Medical College, St. Louis 1902, aged 62, served on the staff of the Evangelical Deaconess Home and Hospital where he died, February 4 of heart disease

Edward Spann Warlick, Asheville, N. C., University of Nashville (Tenn.) Medical Department, 1888, also a druggist, aged 76, died February 5, in the Aston Park Hospital of heart disease

John Thomas Welch, Chicago, Chicago Homeopathic Medical College, 1901, aged 77, died, February 6, of carcinoma of the colon

Walter Balthasar Wellbrock, Lindenhurst, N. Y., Long Island College Hospital, Brooklyn, 1901, at one time village trustee, school physician and mayor of Lindenhurst, visiting physician to Dr. King's Hospital, Bay Shore, aged 67, died February 3, of coronary thrombosis

William Willing Wilkinson & Phoenix, Ariz., Northwestern University Medical School, Chicago, 1901, member of the staff of St. Joseph's Hospital and the Good Samaritan Hospital, aged 73, died, January 27 of injuries received when his automobile was struck by a train

Samuel William Woodhouse Jr., Philadelphia, Jefferson Medical College or Philadelphia, 1895, formerly curator and acting director of the Philadelphia Museum of Art, medical director of the American Red Cross in southern France during World War I, aged 69, died, February 1, of cerebral hemorrhage

DIED WHILE IN MILITARY SERVICE

Thomas Henry Cheavens & Dallas, Texas, Baylor University College of Medicine, Dallas 1928, since 1938 associate professor of clinical neuropsychiatry at his alma mater, where he was assistant in clinical neuropsychiatry from 1929 to 1931, instructor from 1931 to 1935 and assistant professor from 1935 to 1938, member of the American Psychiatric Association, specialist certified by the American Board of Psychiatry and Neurology, Inc., dispensary neuropsychiatrist and associate neuropsychiatrist Baylor and Parkland hospitals, on the staff of the Timberlawn Sanitarium, began active duty in April 1942 as a lieutenant commander in the medical corps of the U. S. Naval Reserve, psychiatrist at the U. S. Naval Hospital San Diego, Calif., where he died, February 23, of hemorrhagic encephalitis, aged 39

John Thompson Shaffer & Sellersville, Pa., University of Pennsylvania School of Medicine, Philadelphia 1929, served as president of the Bucks County Medical Society, on the staff of the Grand View Hospital, an examining physician for the Bucks County Draft Board number 4 at Quakertown, extended active duty began in May 1942 as a captain in the medical corps, Army of the United States, attached to the 321st Air Base Squadron, Kellogg Field, Battle Creek, Mich., where he died, February 21 of coronary occlusion, aged 38

Correspondence

PHYSICIANS MUST VOLUNTEER FROM LARGE CITIES

To the Editor—The editorial entitled "Physicians Must Volunteer from Large Cities" in the March 27 issue of *THE JOURNAL* states that "the responsibility" for the lagging in procurement of medical officers "rests unquestionably on the failure of young available physicians in the large cities of the country, particularly those of the eastern seaboard, to volunteer, and for a solution recommends 'the pressure of public opinion'."

But why are available physicians from the cities not volunteering? These men are no less patriotic than their country cousins and are just as eager to do their part. They resent, however, the fact that many physicians within the draft age are considered "essential" for hospital work, part time teaching, part time research or part time industrial work, an arrangement which permits these men to continue their private practice. The others feel that their obligations and family responsibilities are as great as those of the "essential" men in their own age group. They are particularly disturbed about single men in this deferred category. They know that there are enough qualified men over draft age in cities to take over all part time hospital and clinical work. They feel that whatever medical research is necessary to the war effort should be done on a full time basis, preferably under the direct supervision of the Army and Navy.

The removal of preferential ratings for part time clinical work or teaching would place all physicians within the draft age on an equal footing. They would then have neither reason nor excuse for not volunteering, and it might be unnecessary to call them "before the bar of public opinion" by publishing their names in medical journals.

OCHRONOSIS

To the Editor—In *THE JOURNAL*, March 6, page 784, a reference appearing in my abbreviated paper (Ochronosis of the Sclera and Cornea Complicating Alkaptonuria, *THE JOURNAL*, Dec. 19, 1942) is questioned concerning the first British case of ochronosis. Your correspondent infers incorrectly from Dr. F. M. Pope's article (A Case of Ochronosis with a Note on the Relationship of Alkaptonuria by A. E. Garrod, *Lancet* 1 24, 1906) that "the 11 previously reported (British) cases are mentioned and exact references are listed." The previously reported cases (10) were collected from other countries and can be found in my complete paper appearing in the 1942 Transactions of the Section on Ophthalmology of the American Medical Association. Dr. Pope states (p. 26) "This case is the eleventh reported of this disease and the first from the British Islands. I present in tabular form short abstracts of all the former cases." Only 9 more English cases of ochronosis could be found in my review of the literature. I still believe Cushing's finding that the first British case of ochronosis had been diagnosed as Addison's disease until examined by Osler is worth recording.

JAMES W. SMITH, M.D., New York

PORTAL CIRRHOSIS

To the Editor—In the March 6 issue of *THE JOURNAL*, page 719, in an article by Carl H. Greene entitled "Physiologic Considerations in the Treatment of Portal Cirrhosis," the statement is made that "the patient with cirrhosis frequently shows a reduction in the prothrombin time of the blood which, if pronounced, will cause a tendency to hemorrhage."

It seems apparent that the author meant to express himself in terms of a reduction of the prothrombin level rather than in terms of a reduction of the prothrombin time. It is the reduction of the prothrombin level of the blood which will cause a tendency to hemorrhage. Such a condition, however, is associated with a prolongation of the prothrombin time and not with a reduction of the prothrombin time as mentioned in the author's paper.

Such terminology may seem confusing to the casual reader. For the sake of clarity it should be emphasized that a reduction of the prothrombin level of the blood (hypoprothrombinemia) is synonymous with a prolongation of the prothrombin time causing the well known tendency to hemorrhage. On the other hand, the increase in the prothrombin level of the blood (hyperprothrombinemia) is associated with a reduction of the prothrombin time, causing a tendency to clot formation.

WILLIAM SAHUR, Captain M. C., U. S.

DANGERS OF TALCUM IN THE PERITONEAL CAVITY

To the Editor—For the past decade or more, evidence has been accumulating of the occurrence of so called intraperitoneal granulomas following the accidental implantation of talcum during laparotomy. The talc is shed from the surface of rubber gloves or from collections of the talc powder, which so frequently settles in the tip of the glove fingers and spills therefrom through accidental rips and tears.

Talcum is predominantly a silicate of magnesium and sets up a vicious reactionary adhesive peritonitis, provocative of postoperative intestinal obstruction. I never realized fully the tragic significance of this complication until I encountered it in the postoperative course of my own son.

No one has ever done more than to point out the dangers inherent in talc and to suggest careful depowdering of the surface of the gloves before operating. Consequently we set about to sidetrack the talc evil. After I had made numerous preliminary experiments, Dr. D. J. Verda and Dr. Frank H. Kidd Jr., respectively fellow in surgery and surgical resident in the Barnard Free Skin and Cancer Hospital, interested themselves in the work and have done all of the later experimentation.

This experimentation, although it is not completed in every detail, has now reached the point where we may state with assurance that ordinary cornstarch from every point of view serves as an ideal dusting powder for gloves, causes no undesirable after-effects and is sterilized by ordinary autoclaving.

We are anxious to publish this information in advance of the completion of all our work, so that the basic fact may be available to our armed forces at the earliest possible moment.

MEDICOLEGAL ABSTRACTS

Hospital Service Plans as Insurance—The plaintiff, a nonprofit hospital service plan corporation organized and operated under the appropriate Ohio law relating to such organizations and licensed to do business by the superintendent of insurance of Ohio, sought to enjoin the state treasurer from collecting from it a franchise tax, which a state statute required the treasurer to collect from corporations engaged in the business of insurance. From a decree in favor of the hospital service plan corporation the treasurer appealed to the court of appeals of Ohio, Franklin County.

The plaintiff corporation agreed to act as the agent of eighteen charitable hospitals in Cleveland in the sale to the public of a contract which required the subscriber to pay a stated sum periodically to the plaintiff and entitled him in return to hospitalization for a stated period, if deemed necessary by the subscriber's attending physician, in any of the eighteen hospitals that the subscriber might choose. The plaintiff was to pay the hospital selected by the subscriber designated sums according to the type and length of service rendered to the subscriber. Any surplus remaining in the plaintiff's funds, after paying hospital bills and the cost of administration is held as a reserve for the benefit of the subscribers. This arrangement the treasurer argued, substantially amounted to insurance and in writing such a contract the hospital service plan corporation was writing a contract of insurance and hence was liable for the franchise tax in question. In support of this contention, the treasurer relied on the definition of "insurance company," set out in the insurance code of Ohio, reading, in part, as follows:

The term insurance company as used in this chapter includes every corporation association and society engaged in the business of insurance of any character whatsoever or engaged in the business of entering into contracts substantially amounting to insurance of any character or of indemnifying or guaranteeing against loss or damage or acting as surety on bonds or undertakings.

The treasurer also relied on *State ex rel. Duffy v. Western Auto Supply Company*, 134 Ohio St 163, 16 N E (2d) 256, an Ohio decision, the second paragraph of the syllabus of which reads as follows:

Insurance as related to property and liability is a contract by which one party promises upon a consideration to compensate or reimburse the other if he shall suffer loss from a specified cause or to guarantee or indemnify or secure him against loss from that cause.

The hospital service plan association argued that the contract it issued assures the subscriber service and not indemnity, that it is essential to a true insurance contract that it provide for payment of money to the insured in an amount, defined in the contract, designed to indemnify him for a loss he has suffered. In our judgment, said the appellate court, the contention of the plaintiff that a contract is not one substantially amounting to insurance unless it provides for the payment of money to the subscriber on the happening of a contingency cannot be adopted. Further, the fact that payment under the contract here in question is made to the hospital and not to the subscriber will not prevent the contract from being a contract of insurance. The advantage to the subscriber, if he invokes the benefits of his contract, requires payment in money which is definitely measured by the extent of service rendered to him by the hospital to which he elects to go. It is payable on a contingency, namely, that it is certified by his attending physician that the subscriber requires hospitalization. The minimum payment is not fixed but the maximum payment that may be exacted from the hospital service plan corporation is set forth in the contract. The contract, in probability, is not to indemnify the subscriber because the hospital which he selects does not extend credit to him and, therefore, there is no primary liability on his part which would be essential to make the hospital service plan corporation an indemnifier. The amount which is paid by the subscriber is a charge based on an actuarial determination of the probable risk

incurred in issuing the contract. Although that which is provided the subscriber on the happening of a contingency is, so far as he is concerned, service, yet it is measured by a money consideration payable to the hospital because of the rendering of that service to the subscriber on behalf of the hospital service plan corporation. The language of the section of the insurance code quoted above, in effect, defining a company issuing contract substantially amounting to insurance of any character as an insurance company, is so broad as to require this court to hold that the hospital service plan corporation is an insurance company. The contract in this case in so many particulars amounts substantially to insurance to the subscriber as to require that it be construed to be an insurance contract.

The hospital service plan corporation contended that, even if it was assumed that it was engaged in an insurance business, nevertheless, it was exempt from the payment of the franchise tax imposed on corporations engaged in an insurance business because of a section in the hospital service plan corporation act of Ohio that provides:

Every corporation subject to the provisions of this act is hereby declared to be a charitable and benevolent institution and its funds and property shall be exempt from taxation.

Obviously, said the court the purposes of the plaintiff and the conduct of its business bring it clearly not only within the letter of the act but also within the spirit. In every sense of the term it is a charitable and benevolent institution. The treasurer argued however, that the franchise tax he sought to collect is not levied on the funds or the property of a corporation but is a tax on the right to carry on the nonprofit hospital service plan and that the exemption accorded the plaintiff corporation from all other provisions of the insurance laws, which is granted by the hospital service plan corporation law of the state, does not preclude liability on the part of the hospital service plan corporation for the franchise tax. Charitable hospitals, answered the appellate court, are exempted from all forms of taxation. The hospital service plan corporation here involved acts as an agent for charitable hospitals. The purpose of the subscription contract the plaintiff corporation offers is twofold: first, to make possible necessary hospitalization for a large part of the public at a low cost, and second, to assure in the aggregate the payment of the hospitals of a larger sum for these services than would otherwise be received and thus to enable the hospitals to render a better and more extended general service. The hospital service plan corporation exacts the payment from each such corporation licensed to do business in the state of a fee of \$250 on the filing of an application for certificate of authority and an annual license fee equal to one tenth of one cent for each contract issued by such corporations and then outstanding. The \$250 payment, in itself, is a form of franchise tax and is a prerequisite to the issuance of a certificate which authorizes the hospital service plan corporation to carry on its business. While it is true that it is generally held that a franchise tax is not a tax on property, it should be noted that the language exempting hospital service plan corporations from taxation includes not only property but its funds as well. In view of all of the germane acts, namely, the insurance laws, the taxation statutes and the act relating to hospital service plan corporations, it would seem that it was the legislative intent in enacting the hospital service plan corporation law to exempt such corporations from any liability for taxes of any kind or character or the payment of any sum for the privilege of operating. The legislature as a basis for the granting of certain rights and privileges accorded to nonprofit hospital service plan corporations classified them as benevolent and charitable institutions and set up a comprehensive act under which they were authorized to conduct their business and provided a fee which it deemed adequate in view of the fact that it further provided expressly that the funds and property of such corporation shall be exempt from taxation. This exemption, the court concluded, was intended to be all inclusive.

For the reasons stated, the decree restraining the state treasurer from collecting a franchise tax on the hospital service plan corporation was affirmed.—*Cleveland Hospital Service Association v. Ebright, Treasurer of State*, 45 N E (2d) 157 (C 1942).

CENTRAL SOCIETY FOR CLINICAL RESEARCH

Fifteenth Annual Meeting held in Chicago Nov. 6 and 7, 1912

The President, Dr. ARTHUR R. BARRETS, Mayo Clinic, Rochester Minn., Presiding

(Continued from page 1246)

Effect of Pectin on the Coagulation of Blood in Thrombocytopenic Conditions

Dr. RAPHAEL ISAACS, Chicago. Citrus pectin in the form of powder taken by mouth (in capsules) in doses of 1 Gm. three times a day one half to one hour before meals, has been used in 8 cases of thrombocytopenic purpura over periods of from three months to one year. Two cases were of the idiopathic thrombocytopenic type 2 were secondary to sulfanilamide and sulfathiazole poisoning, 2 of leukemia and 2 others of aplastic anemia. In all these cases there was a cessation of bleeding from the mucous membranes (nose, mouth, uterus) in from twelve to twenty-four hours. The coagulation time of the capillary blood was reduced to less than one minute and the bleeding time lowered to normal. There was rapid but only incomplete clot retraction. There was no change in the number of platelets that could be attributed to the medication. In certain nonthrombocytopenic patients with a tendency to bleed (following extraction of the teeth, menorrhagia) there was a prompt clinical response. No toxic symptoms were noted from much larger doses than those given routinely. While remissions are common in purpuric conditions in these cases cessation of clinical bleeding was noted even though the platelet number was below 30,000 per cubic millimeter.

DISCUSSION

Dr. S. C. WELCH, Chicago. My associates and I have been able to investigate the effect of pectin on coagulation. Pectin in a 2 per cent solution was injected intravenously in the *in vivo* experiments and was added to serum and the like in the Quick system in the *in vitro* experiments. No effect was ascertained. Since for all practical purposes pectin is completely destroyed in the alimentary tract and since we have not been able to show any effect on coagulation Dr. Isaacs's observations do not appear valid to us at this time. If he had given pectin intravenously his results might be explained by the size of the pectin molecule and blocking of the capillary walls. However since pectin was given orally the results can be explained only by an unknown substance which may be present in the crude preparation employed.

Dr. C. J. WATSON, Minneapolis. The available evidence indicates that in thrombocytopenic purpura the main fault is in the platelet-capillary relationship the clotting mechanism is not concerned in the production of petechiae. In a study of this sort it would be valuable to know more about capillary resistance. In other words was the capillary resistance improved. Did the cuff test become negative after the administration of pectin? The same questions might also apply to conditions associated with hypoprothrombinemia as for example in some cases of jaundice and frequently in sprue. There is usually a positive cuff test in cases exhibiting a hemorrhagic tendency. It would be helpful to have objective data with respect to capillary resistance in a study of this sort.

Dr. RAPHAEL ISAACS, Chicago. In our cases the capillary blood clotted quickly and there were clinical remissions. As I understand it Dr. Welch's observations were on the prothrombin time of dogs and normal men while our observations were on the capillary blood coagulation time of patients with thrombocytopenic purpura. It has been reported that the injection of pectin solutions into dogs prolongs their coagulation time. In animals the prolonged coagulation time produced by heparin injections can be neutralized by injection of pectin. Pectin does not hasten the coagulation of blood *in vitro*. In 3 of the patients with pronounced capillary fragility the number of petechiae appearing after the tourniquet test was greatly reduced after pectin therapy.

"Demerol" Clinical Observations

DRS HANS HICHT, PAUL H. NOTH and F. T. YONKMAN, Detroit. One hundred and eleven patients suffering severe pain were treated with "Demerol" (the ethyl ester of 1-methyl-4-phenyl piperidine 4-carboxylic acid). About 75 per cent received an average of 1 Gm over an average period of six days. The remainder received larger total amounts over longer periods up to two hundred and eleven consecutive days. The patients were suffering from a variety of acute and chronic diseases such as arthritis, pleurisy, far advanced carcinoma, hypothalamic lesions (with so called intractable pain), peptic ulcer and angina pectoris. Twelve patients had been receiving morphine or its derivatives from thirty to one hundred and seven days prior to administration of Demerol. The drug was administered orally or intramuscularly in doses of 0.05 to 0.10 Gm from one to eight times daily. One patient received nine hundred and seventy-six injections. The drug was considerably more effective when given intramuscularly. Approximately 80 per cent of the patients obtained satisfactory relief of pain. The degree and duration of the analgesic effect exceeded that of 0.07 to 0.10 Gm of codeine sulfate but was usually less than that of 0.01 Gm of morphine sulfate.

Dizziness, urticaria, vomiting, a cloaking sensation, momentary excitation, euphoria, dryness of the mouth and urticaria were occasionally noted immediately following administration, but in only 5 per cent of all cases were these reactions severe enough to necessitate withdrawal of the drug. Regular urinalysis, blood counts, electrocardiograms and liver function tests showed no alterations which were not explained by the disease from which the patient suffered. A firm, nontender induration of the subcutaneous tissues around the site of injection was frequently observed when the drug was given six to eight times a day over a long period of time.

After prolonged intramuscular administration (0.1 Gm six to eight times daily for periods exceeding one month) sudden withdrawal occasionally resulted in nausea, violent vomiting, profuse perspiration, itching of the skin, irritability, depression and apprehension. These symptoms began a few hours after the drug had been withdrawn and generally lasted for one or two days. During these periods of withdrawal the patients were kept free from pain by various opiates. These reactions could easily be overcome by the use of barbiturates and scopolamine. Symptoms of this kind were never observed following prolonged oral medication.

Demerol, a synthetic substance, is apparently capable of replacing morphine and its derivatives to a certain extent, thus helping to relieve a possible future shortage of opiates. Demerol is not toxic even when given in large doses over a prolonged period. Occasional side effects are observed, and long continued use may be followed by undesirable symptoms on withdrawal.

DISCUSSION

DR FREDRICK F. YONKMAN, Detroit. The authors have emphasized the chemical relation between atropine, morphine and Demerol. The new analgesic can be synthesized readily and, if future results substantiate present experiences with Demerol, this agent represents a distinct contribution to the field of analgesic therapy. Our attention has been directed to the spasmolytic action of Demerol and our results reveal interesting effects of the drug on certain smooth muscle. Pharmacologic studies indicate that relaxed smooth muscle may frequently be stimulated by Demerol, whereas spastic or activated visceral muscle is usually relaxed by this agent. Should the former condition occur, the analgesic action might be of sufficient degree to obviate complaint of discomfort whereas early and rather complete relief might be anticipated if visceral relaxation with analgesia prevailed.

DR JOHN W. SCOTT, Lexington, Ky. It seems that a more accurate measure of relief from pain should be used in making a comparative study such as this, such a method as the Wolff-Hardy apparatus would supply.

DR PAUL H. NOTH, Detroit. No objective method of measuring the analgesic effect was used. The Wolff-Hardy technic provides a standard pain stimulus and is useful in

measuring time of onset, degree and duration of analgesic action. Such studies have been made comparing Demerol with other analgesic drugs. In our study a variable clinical painful stimulus was already present, making the Wolff-Hardy test inapplicable. Therefore the subjective response of the patient was the best measure, under these circumstances, of the effectiveness of the drug.

Treatment of Migraine With Potassium Thiocyanate

DRS E. A. HINES JR and L. M. EATON, Rochester, Minn. In treating a group of patients who had hypertension with potassium thiocyanate, it was noted that many were relieved of their migraine.

Following the observation of the effect of potassium thiocyanate in relieving migraine associated with hypertension, it seemed logical to try the effect of this drug in treating a group of patients who had severe and frequent migraine attacks but who did not have hypertension. To date 27 patients have been treated for periods of three months or longer. In 2 cases it was impossible to obtain a concentration in the blood greater than 2 mg of potassium thiocyanate per hundred cubic centimeters even though as much as 20 grains (1.3 Gm) daily was given. After one month's trial the attempt was discontinued. Neither of these patients noted any change in the frequency or severity of the headaches. Of the group of 27 patients in whom satisfactory blood thiocyanate levels (6 to 12 mg) could be maintained all received some definite relief. In the majority the frequency of the headaches was reduced by 75 per cent. In 7 cases the blood cyanate level was allowed to fall to less than 1 mg per hundred cubic centimeters without the patient's knowledge and there was a definite increase in the frequency of the attacks with subsequent relief when the blood cyanates again reached a satisfactory therapeutic level (6 to 12 mg).

In none of our patients were there any serious toxic manifestations from the drug. It is recognized that potassium thiocyanate is a potentially dangerous drug and in our opinion it should not be used unless the dosage is controlled carefully by frequent determinations of the blood cyanate content.

DISCUSSION

DR EDWARD MASSIE, St. Louis. I should like to ask about the intravenous injections of the drug to patients during the stages of nausea and vomiting.

DR E. A. HINES JR, Rochester, Minn. We have not given potassium thiocyanate intravenously, so we do not know the effect. I have thought of this as a possibility in aborting an attack when the patient has severe nausea and vomiting. I should like to know if any one has given it intravenously to human beings. I know it has been given to animals.

Organic Heart Disease and Electroconvulsive Shock Therapy

DR VERNON L. EVANS, Aurora, Ill. Since the use of electroconvulsive shock therapy was started at Mercyville Sanitarium, no patient has been refused the benefit of this treatment when it was thought to be indicated from a psychiatric standpoint. In many cases the risks taken appeared to be very great but in a series of 302 consecutive cases there have been no deaths from the treatment. No attempt has been made to modify the severity of the convulsions by curare or other drugs.

In the group were 8 patients with presumptive to positive evidence of previous coronary occlusions. The ages of these patients ranged between 52 and 74. In 5 cases there were positive histories of previous coronary occlusions. Seven of the electrocardiograms showed definite inversion of the T waves in leads 1, 2 or 4. The eighth patient was a woman aged 74 who had a complete left bundle branch block. Although there was no history of heart disease this was taken as presumptive evidence of a previous coronary occlusion.

Three patients with auricular fibrillation were treated during the presence of this irregularity. Two of these patients had rheumatic heart disease with histories of previous attacks of decompensation. The other was a woman aged 75 with no his-

tory of heart disease or vascular hypertension. However, she did have generalized arteriosclerosis and moderate enlargement of the heart.

Two patients had hypertensive heart disease as shown by elevated blood pressures (210-180 systolic and 100-90 diastolic) and pronounced left axis deviation on the electrocardiogram. Two patients had probable coronary artery disease because in 1 the PR interval was 0.23 second and in the other there was flattening of the T waves in all four leads. (There was no evidence of myxedema, and the basal metabolic rate was normal.)

With one exception no complications whatever were encountered in the treatment of these patients. The exception was a woman aged 40 who had rheumatic heart disease and a history of one previous episode of decompensation. This patient developed decompensation under treatment and the course of treatment had to be stopped after the tenth convulsion. However, the ascites and edema cleared up with the administration of diuretics and she was given no further shock treatment, as she recovered from her psychosis.

DISCUSSION

DR A. E. BENNETT, Omaha: Most of the depressions in which we get the best results from shock therapy occur in the upper age group. Here the question of cardiovascular complications frequently arises. Dr Evans has shown us that this treatment can be given in the presence of severe heart disease. I have treated many patients in the presence of extreme hypertension and with severe myocardial disease. However, I think a word of caution should be left with respect to this paper because it does carry the implication that the treatment is not serious. Most of the deaths that have occurred with electrotherapy have been coronary deaths. I had one such death occur two hours after an electroshock treatment. I am sure Dr Evans would want us to explain to the relatives of the people to be treated that there is increased risk. Even though we are successful in a large percentage of depressions complicated with organic heart disease, I am sure it increases the hazard.

DR L. N. KATZ, Chicago: This report is important because it seems to indicate that we have been too conservative in our views. A number of patients at the Michael Reese Hospital have been referred from the psychiatric department for electrocardiograms before shock therapy. A number of cases with ST depressions in the limb leads were noted for which no organic cause could be ascribed. It is possible that in psychiatric patients the ST depression sometimes may be on the same basis as the ST depression in normal people associated with fear. Thus there may be abnormalities in the electrocardiogram which are purely functional and not related to organic heart disease.

DR CARROLL W. OSGOOD, Wauwatosa, Wis.: At the Milwaukee Sanitarium we have treated in the neighborhood of 250 cases by electric shock therapy and we feel that the treatment is relatively safe. We have treated a number of patients with electrocardiograms which are suggestive of some coronary disease. We treated one man, aged 67, who had a definite history of a coronary attack several months before. He had severe pain and had been in bed for six weeks. At the time we saw him his electrocardiogram was relatively normal. We saw no ill effects whatever from the treatment. His depression cleared up. He later had a recurrence. Altogether he had three courses of electroshock treatments, about eighteen shocks altogether. We have also treated a number of people with essential hypertension who had pressures of over 200 systolic and 100 diastolic, with no ill effects. We had one death in our series, the patient being an elderly man with some arteriosclerosis. He died suddenly immediately after the shock. An autopsy was held and no abnormality was found on examination of the heart or brain. However, there was a considerable amount of semifluid contents in the stomach, and material having the same appearance in the bronchial tubes. This emphasizes the danger of aspiration.

DR VERNON L. EVANS, Aurora, Ill.: I did not want to imply that this treatment should be given promiscuously. I think that if we continue to give the treatment to patients who are in poor physical condition we shall have deaths. However, as yet we have had none, and it appears that the rate will be small and should not deter us from our efforts to cure people who are seriously ill.

Blood Pyruvic Acid Following Exercise in the Trained and Untrained Individual and in Patients With Heart Disease and Hypertension

DR ZALF A. YANOF, Chicago: It is now firmly established that pyruvic acid and not lactic acid, is the center core of tissue carbohydrate metabolism. This displacement of lactate by pyruvate stimulated this work.

A light standard exercise of fifty ascents in fifty seconds over a two-step contrivance with blood pyruvates at rest and at ten and sixty minutes after the exercise was performed on 11 collegiate wrestlers and track men, 10 sedentary individuals, 10 patients with heart disease of class II-III with enlargement of the heart and 9 class I hypertensive patients without enlargement of the heart but with blood pressures exceeding 200.

Ten minutes after the exercise the mean pyruvate change in the trained group was -5.82 per cent of that of the resting levels, the heart patients +45.75 per cent, the untrained +53.38 per cent, and the hypertensive +63.38 per cent. This difference in the utilization of carbohydrates in the trained individual as opposed to that of the individual whose heart only is working overtime, suggests a clue to the complex chemical changes of "training" and "compensation" and may furnish an index of physical fitness.

The sixty minute mean pyruvate change of the trained group was -15.11 per cent of the resting level, that of the untrained group -5.82 per cent, the hypertensive 0 and the heart patients +16.66 per cent. The order of progression from negative to positive sixty minute changes is more or less in keeping with the cardiac function of these groups. This test could presumably be used to follow the course of a patient with heart disease. This is further supported by the fact that the class III heart patients with the poorest cardiac function had the highest positive sixty minute changes.

Lactate increases only after strenuous exercise whereas in this work pyruvate changed after only light exercise as much as 100 per cent. In addition pyruvate sixty minute changes are more pronounced and circumscribed than lactate sixty minute changes. Pyruvate estimations would appear to be of value in the study of exercise physiology of both trained and untrained individuals and of patients who are not capable of undertaking the strenuous exercise that lactate requires.

DISCUSSION

DR SAMUEL SOSKIN, Chicago: The author expresses all his results in terms of percentage changes. There should be some mention of the absolute values of pyruvic acid with which he was dealing. I should like to ask that these values be given, because I believe that they amount to only a few milligrams per hundred cubic centimeters. In view of this and the inherent errors in sampling and in chemical methods, it is not surprising that the author's data for trained and untrained subjects and for normal and pathologic individuals overlap to a considerable extent. I believe the author also ignores a known physiologic fact when he assumes that the level of pyruvate in the blood is an index of the deficiency of oxygen in the heart and skeletal muscles. It is true that when oxygen is deficient the muscles liberate excessive amounts of pyruvate and lactate into the blood, but it is also true that the normal liver rapidly removes these substances from the blood. The blood level is therefore merely the resultant of these two opposite processes. The slightly higher level of pyruvate and lactate in the blood of patients with heart disease is just as likely to result from some passive congestion of the liver as from any abnormal process in the muscles.

DR ZALF A. YANOF, Chicago: There is some truth in all of the things Dr Soskin said. All I attempted to do was to show what I actually found.

(To be continued)

Current Medical Literature.

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Effect of Iron on Hemoglobin Regeneration in Blood Donors—To determine the average time required for the hemoglobin to return to its original level in blood donors Barer and Fowler gave an iron salt to 89 donors after their second blood donation. The rate of hemoglobin regeneration was increased by 49 per cent so that the average daily hemoglobin increase per hundred cubic centimeters of blood was 0.0772 Gm

and the recovery period was shortened to thirty-five and two-tenths days in comparison to forty-nine and six-tenths days after the first donation without therapy. Under these conditions, 93.5 per cent of the subjects regained their normal hemoglobin level within eight weeks. Iron therapy was administered continuously and some of the subjects gave as many as five donations, subsequent donations were given as soon as the hemoglobin level reached normal. In spite of the continuous iron therapy there was a gradual decline in the rate of hemoglobin formation after each donation until it was being formed at a rate which was no more rapid than it had been without iron therapy. Therefore it seemed as if iron had progressively less effect with continuous administration. There was no evidence of bone marrow exhaustion after repeated donations.

Rheumatoid Arthritis and Heart Disease in Necropsies

—At a postmortem study of the joints of 23 patients with definite rheumatoid arthritis changes Bayles observed that in 6 there were changes in the heart valve leaflets and myocardium similar to those of rheumatic fever. The microscopic lesions of 1 could be considered active and of 5 inactive. Excluding the 1 patient because of definite rheumatic fever and rheumatic heart disease in childhood 22 per cent had rheumatic cardiac lesions. A coincidence, a relationship of rheumatic fever and rheumatoid arthritis or the possibility that the heart disease is related to rheumatoid arthritis might be inferred from the data. Since patients with rheumatoid arthritis die of some cause other than this disease it would be safer and probably wiser to delay a final conclusion until further studies indicate which of the three foregoing situations obtains. In the clinical treatment of the patients the author regarded the cardiac changes as a coincidence of rheumatic heart disease and rheumatoid arthritis.

Meniere's Syndrome—Atkinson suggests two important reasons for the failure of any particular treatment to achieve its hoped for results: laxity of diagnosis and the tendency to regard Meniere's syndrome (recurring vertigo deafness and tinnitus) as a disease *sm. generis*. Cases of the syndrome can be divided into groups according to causation and each group demands its appropriate treatment. An accurate diagnosis demands a careful neurologic examination, Barany tests, appraisal of the relative patency of the eustachian tubes, a thorough general examination to determine the presence of any associated condition, and, when the diagnosis is still not made, idiopathic Meniere's disease is thought of instead of looking for two or more syndromes. This large remaining group of cases can be divided into at least two divisions each with a different cause. Some may have an allergic basis and the others about four fifths of the total, may be insensitive to histamine that is in these the mechanism is primarily vasoconstrictor in contrast to vasodilator of those with an allergic basis. Classification according to the etiologic basis, which is tentative and expresses present knowledge is as follows. A Lesions interfering with the function of the eighth cranial nerve because of (1) lesions of the cerebellopontine angle and (2) degenerative vascular disease. B Lesions interfering with the function of the labyrinth because of (1) alteration in intralabyrinthine pressure (a) from without structure of eustachian tube and (b) from within

increased production of endolymph (primary vasodilatation, allergy, sensitivity to histamine), (2) vascular disease (a) angiospasm, primary vasoconstriction and (b) arteriosclerosis, and (3) "toxic labyrinthitis," that is focal infection

Neurinoma of Facial Nerve in Middle Ear and Mastoid—The thirteenth case of neurinoma of the facial nerve, a rare but clinical entity, is reported by Roberts. Such neurinomas are benign tumors and produce symptoms by extension and pressure. The first symptom is facial paralysis, followed after a period of years by deafness, chronic purulent otitis media and invasion of the mastoid. The tumor is microscopically characteristic of neurinomas or neurofibromas in general and presents a definite pathologic picture.

Treatment of Ichthyosis with Vitamin A—Because of impaired dark adaptation in their 6 patients with ichthyosis and because of the similarities between the accepted cutaneous manifestation of vitamin A deficiency and ichthyosis, Rapaport and his associates submitted them to daily oral doses of 60,000 to 200,000 international units of vitamin A for several months as a therapeutic test for cutaneous improvement. Vitamin A is injectable, containing 100,000 international units of vitamin A and practically no vitamin D in 1 cc. of vegetable oil was administered intramuscularly two or three times a week for several months. The use of this preparation excluded the possibility that vitamin D might have been a factor in the effects obtained. The results were favorable and all patients obtained an amelioration which they deemed worth while. After several months of therapy the texture of the thickened skin became more normal. Cracks and fissures disappeared entirely. Pruritus was also considerably diminished. The scales became thin, superficial and more widely separated. Improvement was noticeable at the end of a month of therapy and was progressive for several months while the treatment was continued, but whenever the vitamin A was withdrawn for an appreciable time the condition of the skin became worse. Dark adaptation also improved with the therapy. The basis of ichthyosis may be some hereditary disorder of vitamin A metabolism. In all but 1 of the 6 patients heredity played a conspicuous role.

Thrombophlebitis Migrans—Birnberg and Hansen present the case of a boy of 14 whose death was definitely due to thrombophlebitis migrans. This, they believe, is the first time the condition has been described in a child. Heparinization was not successful in preventing further venous thrombus formation. Mesenteric thrombosis, the cause of death, was revealed at necropsy. Bacteriologic studies gave no clue to the underlying etiology. However, microscopic study of the eosinophilic inflammation and swelling of the intima of an involved vein suggested that some allergic phenomenon may have been associated with the clinical picture.

Convalescent Blood for Virus Pneumonia—Flexner and Garon believe that their use of whole blood or plasma from convalescent donors for the treatment of 7 patients with atypical (virus) pneumonia definitely reversed the trend of the disease and shortened the convalescence. The response seemed to be specific. They reserved its use only for the seriously ill. They believe that small injections of convalescent serum or plasma might act prophylactically as does measles convalescent serum or whole blood injection in poliomyelitis. In the absence of specific donors blood transfusion from adults may prove beneficial.

- Transplantation of Preserved Tissue in Ophthalmic Surgery. M. Wiener. St. Louis.—p. 53.

Pregnancy Complicated by Poliomyelitis—Peelen suggests that pregnancy and acute anterior poliomyelitis probably occur more frequently than a review of the literature indicates. The 29 cases reported in some detail are reviewed and 2 new ones are added. In addition 28 cases have been reported incompletely. The important conclusions are that the usual course of pregnancy does not change the type of paralysis and complications determine whether interference with the pregnancy is necessary and it has not been proved that intrauterine poliomyelitis occurs. There are only 3 cases which suggest the possibility of intrauterine poliomyelitis. Miller believes that a bilateral clubfoot in 1 was not the result of intrauterine poliomyelitis but rather a congenital deformity and in the other 2 the data available are insufficient to confirm or refute the possibility of intrauterine infection.

*Experimental Trinitrotoluene Poisoning. Effect of Diet. H. P. Himsworth and I. L. Glynn—p. 421

Edema Produced by Cold—The routine cooling of human hands (and feet) by their immersion in water at 41 F. Lewis observed causes the extremities to swell. This increase in their volume occurs in both the cutaneous and subcutaneous tissue and may amount within three hours to as much as 15 per cent of the original volume. The swelling is due mainly to an edema of the tissues judged to be inflammatory from its relatively rapid outpouring and from its relatively high content of protein. The contribution in the form of imbibed water is slight. From this and correlated evidence it seems that cold directly injures the cutaneous and subcutaneous tissue. This effect begins at about 59 to 64.4 F. and increases as the temperature of water descends. The edema that results from long continued immersion of the limbs in cold water should be taken into account as should protein loss, when the effects of exposure to cold on the whole circulation are estimated.

Diet and Trinitrotoluene Poisoning—In an effort to modify the seriousness of the illness that follows exposure to trinitrotoluene Himsworth and Glynn fed white Wistar rats different diets. They observed that typical necrosis of the liver and a profound though not aplastic, anemia occurred in rats exposed to trinitrotoluene when they were on a diet rich in fat while in animals on a high carbohydrate or a high protein diet the ill effects were slight or absent. Chronic trinitrotoluene poisoning in rats was characterized by loss of weight, increased appetite, urinary excretion of high concentrations of trinitrotoluene derivatives, a great decrease in hemoglobin, normoblasts, reticulocytes and polychromatic erythrocytes in the peripheral blood, erythroblastic hyperplasia of the bone marrow, siderosis of the spleen, fatty hepatic infiltration to acute necrosis of the parenchymal cells and loss of hair. The evidence suggests that the effect of the high fat diet is to impede the metabolic ability of the animal to dispose of the trinitrotoluene within its tissues. The resemblance between the effects of trinitrotoluene poisoning in the rat and of that in man is close.

*Perurethral Methods in Benign Prostatic Hypertrophy. T. L. Chapman—p. 14

Cross Desensitization in Allergic Diseases—Maunsell deals with desensitization to the class of allergens called idio-toxins or atopens which cause bronchial asthma, eczema, conjunctivitis and rhinitis. The allergic properties are exerted by food proteins, pollen and other constituents of plants, animal feathers, hair and wool, dust, bacteria and mold. Her investigation is designed to examine the specificity of the anti-allergic mechanism, for which a method of local desensitization of the skin has been studied. The technic was applied to obtain evidence whether in multisensitive patients one allergen can desensitize the skin so that it will no longer react to the others.

This is termed "cross desensitization" as opposed to the "direct desensitization," in which the same allergen is used for desensitizing and retesting. If the desensitization is carried out with two allergens of the same cutaneous activity a reciprocal cross desensitization occurs. If one allergen is stronger than the other the desensitization is unilateral. The occurrence of either reciprocal or unilateral desensitization is independent of the biologic group of the allergens. The desensitization is only a quantitative change and not a qualitative return to a normal response. Observations on the histamine reaction in desensitized areas showed that the decrease in the allergic reaction is not a mere general refractoriness of the tissues but the result of an anti-allergic mechanism. The wide range of cross desensitization suggests that a patient with a multiple sensitiveness does not require a mixed extract but that treatment with a single allergen is sufficient. If various allergens give equally positive reactions, the extract that is obtainable in the strongest concentration should be chosen, so that during treatment the initial dose can be increased ten thousand times or more. An improvement in desensitization must not be expected from finding still more skin reacting allergens but from the production of highly effective extracts and by carrying the desensitization as far as possible.

Accidental Head Injuries—In the course of their work at a military hospital for head injuries Symonds and Russell dealt with a variety of head injuries due to accidents of a kind that also occur in civil life. Their series of 242 acute consecutive cases is not entirely representative of accidental injuries because it does not include those cases in which the severity of the head injury or associated injuries of other parts forbade transfer within three weeks. This explains the low mortality, there were five deaths, and 22 (9 per cent) of the survivors were invalided out of the service. The others, 215, or 89 per cent, were returned to duty. A follow-up showed that a further 11 per cent were invalided later. A long post-traumatic amnesia carried a relatively bad prognosis for return to duty. Analysis of those returned to duty and followed up shows that in 90 per cent treatment (including rehabilitation) was less than three months, there was no difference in the length of treatment between those who had a relapse and those who remained well. The return to duty of 718 patients with chronic head injury, largely selected for admission to a special hospital because of unsatisfactory progress, was more than twice as bad as for the acute cases. There was a correlation between this bad prognosis and a higher incidence in this group of predisposition to mental disorders. The prognosis for return to duty among 111 personnel of the Royal Air Force with acute and chronic head injuries was four times as good as in the total series. The main reason for this relatively good prognosis in flying personnel probably was due to the fact that they were a highly selected group in respect to the absence of a predisposition to mental disorders.

Perurethral Methods in Benign Prostatic Hypertrophy—Chapman has employed perurethral prostatic resection with the Thompson resectoscope since 1938. His results in 100 consecutive cases have been far short of those obtained at the Mayo Clinic. It is chiefly in the benign group that the choice between suprapubic and perurethral methods arises. Six of the 100 men died, in 93 of the 94 survivors urethral micturition was achieved, the 1 patient in which this failed was mentally deteriorated. Micturition was sluggish in 10, and 4 of these were advised to continue with suprapubic drainage. In 3 there was evidence of recurrence of obstruction and in 2 others this was suspected. Function was maintained in the rest. The follow-up period extended up to four years. One instance that was clinically benign at operation later became malignant. Suprapubic prostatectomy offers little or no advantage over a perurethral prostatectomy in the removal of early foci of a malignant condition. Incontinence rarely occurred and then it responded to treatment.

 *Anemia in Kyphoscoliosis F. Reimann—p. 197

Anemia in Kyphoscoliosis, Hemorrhagic Gastritis—Reimann reports 4 cases of severe kyphoscoliosis associated with hypochromic anemia caused by profuse gastrointestinal hemorrhages. Examination of the stomach of 1 patient following resection revealed extensive erosions of the mucosa as the anatomic basis of the gastropathy. The gastric disorder has a causal relationship to the kyphoscoliosis in that the latter produces abnormal spatial conditions. There is a compression of the stomach and duodenum delayed emptying of the stomach a tendency to frequent vomiting, compression of the large abdominal vessels at the root of the mesentery and interference with circulation in the gastric vessels. Delayed emptying and stasis in the gastric vessels cause gastric symptoms and severe hemorrhages. These symptoms disappear in the reclining position and recur when the patient gets up, they have a distinct orthostatic character. The symptoms kyphoscoliosis, hypochromic anemia and erosive hemorrhagic gastropathy are a pathogenic triad which can be designated as anemia in kyphoscoliosis. Knowledge of this syndrome is important in the evaluation of gastric disorders in patients with kyphoscoliosis.

 Allergic Myocarditis and Nephritis in Case of Tuberculous Hilar Adenitis J. Flagg and M. Froehner—p. 922

Interstitial Plasma Cell Pneumonia in Infancy—The Stürmman report observations on cases of interstitial plasma cell pneumonia. An alarming increase became apparent in the fall of 1941. Five infants developed the disorder in short succession and 4 of them died while of the earlier cases about half had recovered. It was surprising that all children who developed this form of pneumonia had been in the same room. Moreover, 1 infant who had been nursed in this room developed interstitial plasma cell pneumonia six weeks after discharge from the hospital. Necropsy of the 4 children who died last verified the diagnosis of interstitial plasma cell pneumonia. The authors observed in all 14 typical cases and a few atypical cases. The cases observed by them differed from others reported in that all the infants with one exception were normal, well developed and not prematurely born. The authors advance the following hypothesis regarding the still obscure pathogenesis. A neurotropic virus damages the respiratory regulation in the diencephalon so that the tonus of the inspiratory muscles, with the exception of the diaphragm, is intensified and the respiratory air is decreased. The extreme inspiratory position of the ribs dilates the pulmonary tissue, which is easily torn at this age. Thus alveolar ruptures or spontaneous pneumothorax is likely. The forced expiration together with the glottis closure increases the intrapulmonary pressure in thrusts. The tears in the alveoli lead to interstitial emphysema, which in turn leads to mediastinal and paratracheal emphysema. Not only air but also detritus is driven into these clefts and in this way the picture of interstitial plasmocytic pneumonia results. Where the detritus originates, whether in the infection or in the torn tissue will require further investigations. The description of the disease still has gaps and it still presents unsolved problems which require further observations.

Serodiagnosis of Undulant Fever—Defining the role which the laboratory should play in the serodiagnosis of undulant fever, Badoux says that the physician will demand (1) a hemoculture (2) an agglutination test and (3) the fixation of

the complement. Hemoculture will be most successful in the recent and febrile cases. Unfortunately the positive results are rare, particularly in case of *Brucella abortus bovis* (Bang) infection which is most frequent in Switzerland. There remain agglutination and fixation of the complement. He made comparative studies with these two tests on 527 patients who were suspected to have brucellosis. The superiority of the fixation of the complement was demonstrated by the fact that it produced 6.45 per cent more positive reactions than did the agglutination test. In conclusion the author calls attention to the high incidence of human brucellosis particularly *Brucella abortus* infection in the French speaking part of Switzerland. He maintains that the serologic methods are often the only procedures which permit a definite diagnosis and that serodiagnosis will be carried out with maximum success by (1) fixation of the complement, (2) the agglutination of Wright and (3) hemoculture.

 Syphilis and Asthma May Syphilis Play Any Role in Development of Asthma J. A. Gruening and O. F. Erdly—p. 963
 Diabetes and Postoperative Hypothyroidism L. C. Fong—p. 981

Pericarditis in Infants—Kreutzer and his collaborators report 8 cases of pericarditis with effusion in infants (2 girls and 6 boys). A clinical and roentgen diagnosis was made in all cases. Electrocardiograms were taken in 4 cases. The disease was purulent in 6 cases and serous and serohemorrhagic in 1 case each. It was secondary to suppurative bronchopulmonary or pleuropulmonary disease in 4 cases to supplicated cervical adenitis in 2 cases and to osteomyelitis of the clavicle in 1 case. Pain and fever were early symptoms. The constant moaning of the patients was interpreted as complaint of pain. Fever was moderate in 1 case acute and of the septic type in the cases of purulent pericarditis and did not appear in the only case of idiopathic pericarditis. Dyspnea cough and cyanosis appeared late in the course of the disease. The authors found that the diagnosis is made by the aforementioned symptoms and by certain physical signs and electrocardiographic changes. The cardiac sounds as heard in the four foci of auscultation may be either weak or normal. The enlargement of the area of cardiac dullness at percussion and the signs of compression of the left lower lobe of the lung by the enlarged pericardium are of pathognomonic value. The enlargement of the x-ray shadow of the heart is also of diagnostic value. The size of the shadow depends on the amount of pericardial liquid. Its form varies with the postural changes of the patient as the liquid is displaced according to the laws of gravity. Radioscopy is also of value. Pulsation of the heart may be diminished, but the so called quiet heart is exceptionally rare. The increase of venous pressure and the consequent engorgement of the jugular veins enlargement of the liver and development of ascites and edema depend on the more or less rapid accumulation of pericardial fluid. As a rule they follow a slow course except in cases of serohemorrhagic pericarditis, in which the pericardial liquid is rapidly collected. The changes of the electrocardiogram consist in elevation of the ST segment especially in the second lead, and of inversion of the T wave in the four leads. The diagnosis is verified by the results of pericardial puncture. Pneumococci streptococci and staphylococci are in order of frequency the bacteria found in suppurated pericarditis. The pericardial fluid does not contain bacteria in cases of idiopathic serous pericarditis. The prognosis is good in idiopathic pericarditis, moderate in the serohemorrhagic form of the disease and fatal in suppurative pericarditis. The prognosis of suppurative pericarditis can be improved by early therapy consisting of pericardiectomy and administration of sulfanilamide. The patients with serous (idiopathic) and serohemorrhagic pericarditis were reported by the author cured. Four patients died from suppurative pericarditis. Two patients died from renal abscess complicating suppurative pericarditis.

Book Notices

Recent Advances in Anesthesia and Analgesia (Including Oxygen Therapy) By C. Langton Hewer M.B. B.S. D.A. Senior Anesthetist St. Bartholomew's Hospital London. Fourth edition. Cloth. Price \$5.00. Pp. 311 with 135 illustrations. Philadelphia: Blakiston Company, 1943.

The author, who is a well known British anesthetist has gathered from the literature (largely British) much relatively recent material. For the most part he indicates his agreement or disagreement with opinions expressed in the literature. The fields considered are theoretical aspects of inhalation anesthesia, premedication, nitrous oxide and the hydrocarbon gases, carbon dioxide and helium, modern apparatus for the administration of the gas anesthetics, recent work on the ethers, the halogen containing anesthetics, recent developments in endotracheal intubation, the explosion risk in anesthesia, intravenous anesthesia, general aspects of local anesthetic drugs used in local analgesia, recent advances in the technique of local analgesia, the present position of spinal analgesia, collapse and resuscitation, anesthesia for cranial and dental surgery, anesthesia for endoscopy and nasal and oral surgery and use of suction, anesthesia and analgesia for thyroid, thoracic and abdominal surgery and in obstetrics with comments on resuscitation of the newborn, anesthetic sequelae, psychological aspects of anesthesia and analgesia and oxygen therapy. The book is especially interesting to the experienced anesthetist. It reflects the rapid advancement in anesthesiology. It is also valuable to the inexperienced anesthetist in that it serves as a guide to his reading. This small book is similar to the annual reports published in certain fields in order to record recent progress. It includes many practical points that may be applied clinically. However many who read it will feel that they would gladly trade much of the material in the book, which has been gathered from the literature for more information from the author on how he anesthetizes patients.

The Antigonadotropic Factor with Consideration of the Antihormone Problem. By Bernhard Zondek and Felix Sulman. Hebrew University, Jerusalem. Cloth. Price \$3. Pp. 185. Baltimore: Williams & Wilkins Company, 1942.

The authors have chosen to discuss a controversial subject. The review is thorough and gives much data, pro and con, based on experimental evidence both animal and human. Historically, Long and Evans in 1921-1922 found that protracted treatment of female infantile rats with anterior pituitary extracts induced the formation of atretic corpora lutea, atrophy of the ovaries and failure of estrus. Zondek in 1930 reported that female animals subjected to prolonged treatment with gonadotropic extract showed definite involution of the genital organs. In 1929 Lee, Teel and Gagnon reported failure of continued stimulation following prolonged treatment with thyrotropic factor. In 1934 Collip and Anderson postulated the presence of an antithyrotropic hormone. Since then antihormonal reactions have been reported for almost all the known hormones, especially those having a protein structure, such as the pituitary, the parathyroid, the adrenal and the pancreatic.

Zondek and Sulman state that "one of the main difficulties of antihormone research is that hormone preparations are not available 100 per cent pure. These contain the hormone together with protein contaminants which compete with the hormone in serological ability to form antibodies. They conclude "We feel that the arguments presented suffice to establish the view that antiprolan formation is an immune reaction. Up to the present, only protein containing hormones, especially the anterior pituitary (and cortin) have been found to evoke the formation of antihormones. It seems to have been proved that antihormone formation does not occur from protracted treatment with the steroid hormones, or with insulin, adrenalin, thyroid hormone (thyroxin), pitressin or pitocin. The theory is here advanced, therefore, that the antigonadotropic factor represents a new type of blood substance which, though closely related to the immune bodies, does not give the *in vitro* reactions which generally characterize an antibody. It seems likely,

furthermore, that also antifactors other than the antigonadotropic factor are immune bodies, the antigonadotropic substances in any case are not 'hormones with reverse properties', they are immune bodies which lack a visible *in vitro* reaction. Their general behavior *in vivo* and *in vitro* leads to their classification as a group of immune bodies of a character hitherto unknown in serology."

While this book indicates a comprehensive knowledge of the subject 'antihormones' and contains valuable information for investigators who are doing animal research, it is too complicated for the clinician. The subject is furthermore too theoretical to have practical clinical value now.

The Relation of Certain Anomalies of Vision and Lateral Dominance to Reading Disability. By Phillip W. Johnston Ph.D. Research Consultant, Mass. Dept. of Public Health, Boston. Monographs of the Society for Research in Child Development, Volume VII, No. 2 (Serial No. 32). Paper. Price \$1.50. Pp. 154 with 31 illustrations. Washington, D.C.: National Research Council, 1942.

The investigation was designed to determine the importance of various visual functions as factors in reading disability. The factors considered were visual acuity, muscle balance and anomalies of ocular dominance. A group of school children in Reading, Mass. were submitted to tests for these functions, and the results were compared with their record of reading accomplishment. The use of the various tests is accurately described. The Massachusetts vision test was used in estimating visual acuity with certain modifications, including a method of using the Landolt broken ring test in a way which seems more practical than any yet described. Variations in this test were minimized when standardized methods were employed and when one particularly well qualified member of the school staff was employed to do all the testing. Results indicated a probable association between latent hyperopia and low reading achievement. No such relationship was found between reading disability and heterophoria as found in this group.

Ocular dominance was determined by a battery of ten tests performed on each child, and right or left handedness was determined by a similar series of tests. The results are treated in an elaborate statistical manner with profuse use of algebraic formulas and graphs which are confusing to the reader with an ordinary medical education. Out of it all, however, comes the sober conclusion that no correlation between incongruities of ocular dominance and handedness and cases of reading disability could be found. The series in which the latter series of tests was made was not a large one, but the conclusion if corroborated will be of importance, since many educators, without much evidence, have placed great stress on such a probable relationship and this is perhaps the most accurately controlled series of observations which has been made on the subject.

The Biological Action of the Vitamins. A Symposium. Edited by E. A. Evans Jr. Associate Professor of Biochemistry, the University of Chicago. Cloth. Price \$3. Pp. 227 with 30 illustrations. Chicago: University of Chicago Press, 1942.

Under present conditions it probably will be a long time before such another symposium is held as the one on respiratory enzymes at the University of Wisconsin, and its sequel on the biologic action of the vitamins at the University of Chicago late in 1942. The present volume is a companion piece to the volume on respiratory enzymes published under the editorship of Prof. Perry Wilson of the University of Wisconsin. It consists of fourteen essays on the vitamins, each one being an important presentation by a distinguished investigator. The general tone of the papers is brought out in the initial paper on "The Biological Action of the Vitamins" by C. A. Elvehjem, in which he has called attention to the change in direction of research on the vitamins. Whereas much of the earlier work on vitamins involved a study of growth in animals, the present direction is toward a study of the action in tissues. Here the work has been made possible by advances in the field of enzyme chemistry and thus these two phases of biochemistry have been brought together, at least with regard to some of the members of the vitamin B complex. Thus thiamine, riboflavin and nicotinic acid in combination with other substances have been demonstrated to be essential components of enzyme systems concerned with the oxidation of foodstuffs. Oschoa has written

on cocarboxylase, Norman Jolliffe on the clinical aspects of vitamin B₁₂, Paul Gyorgy on riboflavin deficiency in the human being, and David T. Smith on nicotinic acid and pellagra. S. Lephovsky has contributed a brief discussion of pyridoxine, R. J. Williams has written on pantothenic acid, Edgar S. Gordon on pantothenic acid in human nutrition and Vicent du Vigneaud on biotin. Wendell H. Griffith, now on foreign service with the Army, has given an excellent presentation of the facts about choline. Franklin C. McLean has presented new points of view about the economy of phosphorus in the animal organism and D. W. MacCorquodale and H. P. Smith and E. D. Warner have written about vitamin K. Persons interested in any one of these phases of vitamins will find this book exceedingly useful and stimulating.

Climate Makes the Man. By Clarence A. Mills, M.D., Ph.D., Professor of Experimental Medicine, University of Cincinnati. Cloth. Price \$3. Pp. 320. New York & London: Harper & Brothers, 1942.

The title of this well written book aptly characterizes the content. Designed for the nonprofessional reader, it presents a survey of the many interrelated fields in which climate assumes a role—a role much greater than the modern medical man and more particularly the modern medical scientist has cared to consider. For this very reason this popular survey, while purely nonscientific from the point of view of omitting all references to the literature, can be most useful to the physician who may still have sufficient time and detachment to think of the causes of disease as multiple rather than single.

Physicians of an earlier generation were more than conscious of this. In von Leyden's biography a chance remark on the health conditions of Bucharest is pertinent. "For despite its beautiful situation Bucharest is by no means among the healthier cities, the climate is not favorable, in winter temperatures fall to -24 C and during the heat of summer reach 48 C among the patients who consulted me were many with heart disease (nonrheumatic in character) which leads me to conclude that the cause must be associated with the climatic conditions." Coming from the north of Europe, the more brusque and taxing changes in the weather of the Balkans and Russia impressed the medical visitor. Page Hitler for confirmation!

"Climate Makes the Man," finding favor with the reading public, will indirectly awaken the interest of the physician. Patients are living organisms that are conditioned by the weather and the climate. Their diseases reflect these changing conditions, and the physician who evaluates the sum total of the environmental factors becomes a better physician. But this is not yet taught in the medical schools.

The Vertebrate Eye and Its Adaptive Radiation. By Gordon Lynn Walls, Research Associate in Ophthalmology, Wayne University College of Medicine, Detroit. Bulletin No. 19, Cranbrook Institute of Science. Cloth. Price \$6.50. Pp. 785 with 198 illustrations. Bloomfield Hills, Michigan: Cranbrook Institute of Science, 1942.

This book is the nineteenth bulletin of the Cranbrook Institute of Science, a massive tome with illustrations galore. The material deals with the various phases of the vertebrate eye. The first part is labeled "basic." It treats of light and its properties with especial reference to perception by an eye. The eye itself, the human eye is then discussed and dissected from all points, starting with embryology, passing through the gross and microscopic anatomy, and finishing with the physiology of vision. This part is well written in plain language. The second part is the ecologic, in this are discussed the necessary adaptations that the visual apparatus has undergone and is still undergoing so that the parent organism may survive under various conditions. To the clinical ophthalmologist, much of this section will be entirely new and he will be surprised how much of this applies to his daily routine. The third section is labeled "synoptic," which Webster defines as "affording a general view of a whole or of its principal parts." In this are described the eyes and their why and wherefore of birds, beasts, reptiles and fishes. Here too the clinician will find much of interest. While this book is essentially for reference, the average thinking physician can read it with pleasure and profit. The bookmaking is good, as are the illustrations, which are largely diagrammatic and hence easily understandable.

Pesquisas sobre a febre amarela. Por el Dr. Hermínio Linhares, biólogo do Instituto Oswaldo Cruz. Tese. Paper. Pp. 78. Rio de Janeiro: Imprensa Nacional, 1941.

This is a thesis written for the degree of doctor of medicine from the University of Brazil to be considered by the faculty of that institution in the manner of and modeled after French schools of medicine. During 1939, 1940 and for a few months of 1941 the author worked in the yellow fever service of the Ministry of Education and Health of Brazil and through that organization in cooperation with the International Health Division of the Rockefeller Foundation. It seems to be a careful study of the yellow fever virus. The experimental animals used in the study were chicks, mice and cats, the primary purpose was to study passages of the virus from animal to animal routes by which these animals are susceptible organs within the body of the animals in which the virus may be found after specific periods of time, the effect on the virus of avitaminosis B and the periods of time following inoculation in which immune bodies appear, correlated with age and route of introduction. It is pointed out that following intradermal inoculation of the virus it is not impossible that infected mosquitoes may be responsible for the spread of the virus among chicks and perhaps other very young birds which suggests a possible reservoir. The volume is bound in durable paper, written in the Portuguese language and well printed on permanent glossy paper. Comprehensive English summaries are appended to each of four sections. Included in the book are numerous well designed and informative tables and several graphs setting forth in detail the results of the experiments.

Laboratory Handbook for Dietetics. Compiled by Corrin Thompson, Head Dietitian, Municipal Hospitals, Winnipeg, Canada, under the direction of Margaret A. Olson, Associate Professor, Foods and Nutrition, Iowa State College, Ames, Iowa. Paper. Price \$1.25. Pp. 73. Minneapolis: Burgess Publishing Company, 1942.

This is an 8 by 11 spiral book, prepared to furnish students with convenient tables for use in evaluating diets. The table of dietary allowances contains the figures of the Committee on Foods and Nutrition of the National Research Council, Nov. 1941. The sources from which the data quoted in the table of proximate composition of some American foods were obtained are all listed and are known to be reliable. The table is ample for ordinary use. The last fifty pages of the book are recipes in tabular form to be evaluated by the student. Its purpose is to require the student to analyze food combinations and recognize the wide difference in the proximate composition of the final product. These tables omit space for fat and carbohydrate. Moreover, an equal number of blanks for the student's own recipes would give the book broader use. Tables giving the chief food sources of each of the specific nutrients or space where the student might record these would also be of great value.

La toracoplastia ántero lateral elástica de Monaldi. Por Jacinto Foglio, Tesis de doctorado, Universidad Nacional de Buenos Aires, Facultad de Ciencias Médicas, Escuela de Medicina. Paper. Pp. 96 with 39 illustrations. Buenos Aires: Establecimiento tipográfico de A. Cuidi Buffarini, 1942.

This gives an excellent account of the indications, operative methods and results of Monaldi's operation. The views of the Italian school—Forlanini, Morelli and Monaldi—are clearly summarized. The conclusions of the author are supported by numerous clinical histories and reproductions of x-ray plates, and the literature on the subject is thoroughly quoted.

Páginas clínicas. Por el Doctor Lazaro Mendoza, profesor de clínica médica (semiología y diagnóstico), Universidad de El Salvador. San Salvador. Paper. Pp. 166. San Salvador: Imprenta Nacional, 1942.

The author, professor of medicine in the University of Salvador, has selected 36 interesting and varied cases which range from malaria to cancer of the pancreas. A devout admirer of French medicine, he deals with his problems in a light, picturesque and yet penetrating manner. The most interesting chapters are the fourteenth, fifteenth and sixteenth, in which he comments on the first cases of typhus fever, murine type, ever described in his country.

Queries and Minor Notes

THE ANSWERS HERE FURNISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

COLOR BLINDNESS OF PHYSICIAN AND MILITARY SERVICE

To the Editor—One of our boys in medical school is color blind. As I understand the military requirement, that would bar him from military service. What effect will that have on him in general practice of medicine and surgery?

Robert H. Kerr, M.D., Alma, Neb.

ANSWER—Color blindness is not a bar from army service in the medical corps. Those who are color blind are not acceptable for general military service but can qualify for limited military duty. It is believed to be barred in the Navy Medical Corps as it is in aviation service. It does offer certain handicaps in medical work chiefly in certain laboratory procedures, but there are a number of physicians who are red-green blind (the common anomaly) who have done excellent work and claim to have noticed little, if any, inconvenience from this defect.

PHARMACOLOGICAL EFFECTS OF YOHIMBINE

To the Editor—I have noted in some literature from a manufacturing pharmaceutical concern relative to the use of yohimbine that vertigo, nervous excitation, palpitation, insomnia, and headache indicate a reduction or discontinuance of the remedy. With 1 patient I have noted most of the symptoms mentioned quite definite with even a small dose. Have you any data concerning the physiologic action of yohimbine on the circulatory, respiratory, nervous, or other body systems which might explain the symptoms noted?

M.D., New Mexico

ANSWER—The undesirable symptoms and reactions reported after yohimbine are correctly emphasized as those indicating toxicity and are apparently directly associated with a fall in blood pressure. It has been shown by Hamet (*Compt. rend. Acad. d. sc.* 93:1274 [Nov. 27] 1925) in Europe and by Young, Yonkman, and their co-workers in this country that the alkaloid and some of its derivatives produce an abrupt and pronounced fall in blood pressure, respiratory changes and occasional skeletal tremors when injected intravenously into anesthetized cats and dogs. In cats a dose of 3 to 7 mg. per kilogram produces a paralysis of salivation controlled by the cervical sympathetic nerve as demonstrated by failure of secretion when the nerve is electrically stimulated after yohimbine (Yonkman, F. G., and Young, A. G. "The Antisymphatheticomimetic Effect of Ethyl Yohimbine on Salivation and Mydriasis," *J. Pharmacol. & Exper. Therap.* 63:40 [May] 1938). This sympatholytic action, together with the well known epinephrine reversal effect elicited by the drug (Young, A. G., and Yonkman, F. G. "Further Studies of the Chemotherapy of Yohimbine Compounds," *ibid.* 57:150 [June] 1936), suggested the use of yohimbine in experimental hypertension of the type produced in dogs by Page's technique of kidney envelopment. The alkaloid, when intravenously administered, is capable of acutely lowering tension and is still able to reverse the effect of epinephrine in the hypertensive state (Chase, H. S., Yonkman, F. G., and Lehman, A. J. "The Effect of Ethyl Yohimbine in Experimental Hypertension," *ibid.* 72:6 [May] 1941).

After oral treatment of hypertensive dogs with yohimbine it was found (Jacobs, J., and Yonkman, F. G. "The Effect of Yohimbine Hydrochloride in Trained Unanesthetized Dogs with Experimental [Page Type] Hypertension to be published") that an initial dose of 10 mg. per kilogram produced after five to fifteen minutes profound salivation, panting, increased pulse rate, fall in blood pressure, generalized tremors and weakness to the point of collapse. The animals were evidently in real distress. However, beginning with smaller daily doses of 1 to 3 mg. per kilogram the undesirable symptoms and reactions were diminished or obviated, apparently an early tolerance seems to be developed to some extent, but pressure decline persisted as long as treatment continued for twelve months or more.

Clinically, 1 to 2 mg. per kilogram can be tolerated orally by most patients. The described side reactions should be carefully avoided if possible and one must always anticipate the hyperreactive patient such as the one described. The early treatment of essential hypertension on a sympatholytic basis seems promising, but acceptance of this procedure awaits further clinical study.

INJECTION OF HEMORRHOIDS AND OBTURATOR NERVE PARALYSIS

To the Editor—Are there recorded instances of bilateral obturator nerve paralysis following hemorrhoidal injections? I should appreciate knowing the best procedure or treatment used in such cases. M.D., Nebraska

ANSWER—The obturator nerve arises from the lumbar plexus by a fusion of the three anterior divisions of the plexus which are derived from the second, third and fourth lumbar nerves. Emerging from the medial border of the psoas near the brim of the pelvis it passes on the lateral side of the hypogastric vessels and ureter and descends through the obturator foramen to the medial side of the thigh. The symptoms of isolated paralysis of this nerve which is rare are impairment of external rotation and adduction of the thigh, difficulty in crossing the legs and a small insignificant sensory loss.

Injection of hemorrhoids occasionally causes an ascending thrombosis of the superior hemorrhoidal vein. For several days the patient feels pressure and fullness in the pelvis, and to digital palpation a sensitive leathery thickening may be felt extending 2 or 3 inches upward from the site of injection. Rarely an embolus into the portal system notably into the liver may occur. The inferior and middle hemorrhoidal veins drain into the internal pudic and from here into the hypogastric vein. No case of obturator paralysis has been recognized from a thrombosis of the hypogastric vein, although in a septic ascending thrombosis with abscess formation one can observe radiation of pain into gluteal or sciatic territory. In order to explain a bilateral paralysis either the obturator nerve must be involved through a bilateral hypogastric thrombosis or the block must occur in the vertebral canal into which the anterior vertebral veins may drain blood from the hemorrhoidal venous plexus.

These data are given as a basis for a possible anatomic connection between the injection of hemorrhoids and the paralysis of the obturator nerves. Whether such a connection can really be assumed would depend on data which the correspondent does not submit, namely type of rectal lesion treated, symptoms following injection and interval between the injection and the paralysis. Other causes of paralysis, namely pressure on the pelvic brim, intrapelvic abscesses and position of the patient on the operating table, should be considered. Finally, a neurologic lesion associated with involvement of other nerves, mostly the femoral, must be thought of. Treatment cannot be suggested unless the cause of the lesion can be more closely defined.

REFRACTORY PARATYPHOID A INFECTION OF LIVER AND BILE TRACT

To the Editor—A man aged 29 has had an infection with paratyphoid A organisms for eighteen weeks. He has a septic type of fever, below normal in the morning and up to 104 F. every night. Every possible focus of infection except the liver and the gallbladder has been eliminated where on laparotomy small abscesses were found throughout the liver. The gallbladder itself contained bile which had numerous pus cells and paratyphoid A organisms. Have there been any reports of liver abscess complicating paratyphoid A infection or any in which drainage of the common bile duct has afforded cure? The gallbladder has already been drained, the bile flowing freely for three weeks without appreciable effect on the fever. The tube has since fallen out and drainage has ceased. While the gallbladder was draining the patient's fever was lower but since it has stopped draining his chills have returned and his temperature has resumed its high level. Sulfathiazole, sulfadiazine and azosulfamide have been tried without much effect. Sulfapyridine reduced the temperature for two days but had to be discontinued since the patient could not tolerate it. The main question now is whether the common bile duct should be drained again and the entire bile flow redirected outside the body.

H. D. Cheifetz, M.D., Montreal, Que.

ANSWER—The occurrence of multiple abscesses of the liver has been observed in the typhoid infections. It is not common but is more common than solitary abscess of the liver. The multiple abscesses usually follow a suppurative cholangitis or a pyelophlebitis following appendical involvement. It seems likely in this case that the primary difficulty lies in the liver and that the gallbladder is secondarily infected. In such a situation drainage of the gallbladder would afford some relief but would not adequately drain the foci in the liver. All of this could easily account for the septic type of fever although other foci should be sought. Thrombophlebitis elsewhere and pyelitis may cause a similar course.

It seems unlikely that further drainage of the gallbladder would effect a cure. At least other methods would seem indicated first. In such a case as this it is necessary to grasp at straws. While sulfaguandine therapy has not yet received sufficient support to warrant its widespread adoption it would certainly be worth a trial. Convalescent serum has had some support in the past and would certainly be harmless. Immuno-transfusion, that is, transfusion of whole blood from an immune donor, is worth consideration. If all these measures fail surgical drainage of the biliary tract may be reconsidered.

on cocarboxylase, Norman Jolliffe on the clinical aspects of vitamin B₁, Paul Gyorgy on riboflavin deficiency in the human being, and David T. Smith on nicotinic acid and pellagra. S. Lepkovsky has contributed a brief discussion of pyridoxine, R. J. Williams has written on pantothenic acid, Edgar S. Gordon on pantothenic acid in human nutrition and Vicent du Vigneaud on biotin. ANSWER—The undesirable symptoms and reactions reported after yohimbine are correctly emphasized as those indicating toxicity and are apparently directly associated with a fall in blood pressure. It has been shown by Hamet (*Compt rend Acad d sc 93* 1274 [Nov. 27] 1925) in Europe and by Young, Yonkman and their co-workers in this country that the alkaloid and some of its derivatives produce an abrupt and pronounced fall in blood pressure, respiratory changes and occasional skeletal tremors when injected intravenously into anesthetized cats and dogs. In cats a dose of 3 to 7 mg per kilogram produces a paralysis of salivation controlled by the cervical sympathetic nerve as demonstrated by failure of secretion when the nerve is electrically stimulated after yohimbine (Yonkman, F. F., and Young, A. G. The Antisymphatheticomimetic Effect of Ethyl Yohimbine on Salivation and Mydriasis, *J Pharmacol & Exper Therap* 63 40 [May] 1938). This sympatholytic action, together with the well known "epinephrine reversal" effect elicited by the drug (Young, A. G., and Yonkman, F. F. Further Studies of the Chemotherapy of Yohimbine Compounds, *ibid* 57 150 [June] 1936), suggested the use of yohimbine in experimental hypertension of the type produced in dogs by Page's technic of kidney envelopment. The alkaloid when intravenously administered, is capable of acutely lowering tension and is still able to reverse the effect of epinephrine in the hypertensive state (Chase, H. S., Yonkman, F. F. and Lehman, A. J. The Effect of Ethyl Yohimbine in Experimental Hypertension, *ibid* 72 6 [May] 1941).

After oral treatment of hypertensive dogs with yohimbine it was found (Jacobs, J., and Yonkman, F. F. The Effect of Yohimbine Hydrochloride in Trained Unanesthetized Dogs with Experimental [Page Type] Hypertension to be published) that an initial dose of 10 mg per kilogram produced after five to fifteen minutes profound salivation, panting, increased pulse rate, fall in blood pressure, generalized tremors and weakness to the point of collapse. The animals were evidently in real distress. However, beginning with smaller daily doses of 1 to 3 mg per kilogram the undesirable symptoms and reactions were diminished or obviated, apparently an early tolerance seems to be developed to some extent, but pressure decline persisted as long as treatment continued for twelve months or more.

Clinically, 1 to 2 mg per kilogram can be tolerated orally by most patients. The described side reactions should be carefully avoided if possible and one must always anticipate the hyperactive patient such as the one described. The early treatment of essential hypertension on a sympatholytic basis seems promising, but acceptance of this procedure awaits further clinical study.

INJECTION OF HEMORRHOIDS AND OBTURATOR NERVE PARALYSIS

To the Editor—Are there recorded instances of bilateral obturator nerve paralysis following hemorrhoidal injections? I should appreciate knowing the best procedure or treatment used in such cases. M.D. Nebraska

ANSWER—The obturator nerve arises from the lumbar plexus by a fusion of the three anterior divisions of the plexus which are derived from the second, third and fourth lumbar nerves. Emerging from the medial border of the psoas near the brim of the pelvis, it passes on the lateral side of the hypogastric vessels and ureter and descends through the obturator foramen to the medial side of the thigh. The symptoms of isolated paralysis of this nerve which is rare are impairment of external rotation and adduction of the thigh, difficulty in crossing the legs and a small insignificant sensory loss.

Injection of hemorrhoids occasionally causes an ascending thrombosis of the superior hemorrhoidal vein. For several days the patient feels pressure and fullness in the pelvis, and to digital palpation a sensitive leathery thickening may be felt extending 2 or 3 inches upward from the site of injection. Rarely an embolus into the portal system notably into the liver may occur. The inferior and middle hemorrhoidal veins drain into the internal pudic and from here into the hypogastric vein. No case of obturator paralysis has been recognized from a thrombosis of the hypogastric vein although in a septic ascending thrombosis with abscess formation one can observe radiation of pain into gluteal or sciatic territory. In order to explain a bilateral paralysis either the obturator nerve must be involved through a bilateral hypogastric thrombosis or the block must occur in the vertebral canal into which the anterior vertebral veins may drain blood from the hemorrhoidal venous plexus.

These data are given as a basis for a possible anatomic connection between the injection of hemorrhoids and the paralysis of the obturator nerves. Whether such a connection can really be assumed would depend on data which the correspondent does not submit, namely type of rectal lesion treated, symptoms following injection and interval between the injection and the paralysis. Other causes of paralysis, namely pressure on the pelvic brim, intrapelvic abscesses and position of the patient on the operating table, should be considered. Finally, a neurologic lesion associated with involvement of other nerves, mostly the femoral, must be thought of. Treatment cannot be suggested unless the cause of the lesion can be more closely defined.

REFRACTORY PARATYPHOID A INFECTION OF LIVER AND BILE TRACT

To the Editor—A man aged 29 has had an infection with paratyphoid A organisms for eighteen weeks. He has a septic type of fever below normal in the morning and up to 104 F every night. Every possible focus of infection except the liver and the gallbladder has been eliminated where on laparotomy small abscesses were found throughout the liver. The gallbladder itself contained bile which had numerous pus cells and paratyphoid A organisms. Have there been any reports of liver abscess complicating paratyphoid A infection or any in which drainage of the common bile duct has afforded cure? The gallbladder has already been drained, the bile flowing freely for three weeks without appreciable effect on the fever. The tube has since fallen out and drainage has ceased. While the gallbladder was draining the patient's fever was lower but since it has stopped draining his chills have returned and his temperature has resumed its high level. Sulfathiazole, sulfadiazine and azosulfamide have been tried without much effect. Sulfopyridine reduced the temperature for two days but had to be discontinued since the patient could not tolerate it. The main question now is whether the common bile duct should be drained again and the entire bile flow redirected outside the body.
H. D. Cheifetz M.D. Montreal, Que.

ANSWER—The occurrence of multiple abscesses of the liver has been observed in the typhoid infections. It is not common but is more common than solitary abscess of the liver. The multiple abscesses usually follow a suppurative cholangitis or a pyelophlebitis following appendical involvement. It seems likely in this case that the primary difficulty lies in the liver and that the gallbladder is secondarily infected. In such a situation drainage of the gallbladder would afford some relief but would not adequately drain the foci in the liver. All of this could easily account for the septic type of fever, although other foci should be sought. Thrombophlebitis elsewhere and pyelitis may cause a similar course.

It seems unlikely that further drainage of the gallbladder would effect a cure. At least other methods would seem indicated first. In such a case as this it is necessary to grasp at straws. While sulfaguanidine therapy has not yet received sufficient support to warrant its widespread adoption, it would certainly be worth a trial. Convalescent serum has had some support in the past and would certainly be harmless. Immuno-transfusion, that is, transfusion of whole blood from an immune donor, is worth consideration. If all these measures fail, surgical drainage of the biliary tract may be reconsidered.

RECURRENT ULCERS AND NEUROLOGIC DISTURBANCE OF LEG

To the Editor—A woman gives a history of being well until two years ago at which time she thought she hurt her left foot at the ankle and an ulcer developed soon afterward. This ulcer did not heal for several months and soon after it did heal another developed. These ulcers have been coming and going ever since always being somewhere on the lower part of the left leg near the ankle. At present she has a large craterlike ulcer on the inner aspect of the ankle which has been present since July and which will not heal in spite of therapy used. She has a number of large scars on her arms which she says developed from sores following mosquito bites last year. Also soon after her first ulcer the left leg became numb and began to swell. When first seen by me in the summer her left leg was cold with no sensation to pain or touch up to the knee. She is unable to move any part of the leg below the knee. The knee reflex (patellar) is normal. The trophic ulcer now is constantly increasing in size. In the early part of September she developed severe stomatitis with patchy reddened areas covered with a grayish exudate. Smears were negative for Vincent's organism. The gums also became involved and are much swollen and bleed easily. The condition has remained the same since with but little improvement. A spinal tap done in September revealed a normal cell count no increase in pressure normal globulin and sugar normal colloidal gold and no xanthochromia. The red blood cells number 3 470 000 hemoglobin 65 per cent white blood cells 13 800 polymorphonuclear cells 82 per cent, lymphocytes 16 per cent metamyelocytes 2 per cent. She has headaches in the back of the head three or four times a day. The x-ray examinations of the chest and the bones of the leg are negative except for density due to disuse. Pulsation above the ankle is not felt the foot being swollen. No external pain sensation is present although there is some deep sensation when exploring the ulcer crater. There is no sensation to hot or cold water. The patient suffers from constipation. The menstrual periods vary from six weeks to six months apart are scanty, and usually last only one to two days. The blood pressure is 132/80 the urine normal the Wassermann reaction negative agglutinations for typhoid undulant fever and tularemia are negative. Possible syringomyelia or vitamin deficiency are considered. The patient has been given vitamin B complex nicotinamide ascorbic acid liver extract ferrated liver and the like at one time or another contrast baths and other treatments, but so far none have done any good.

Carl Baumgartner M.D. Bismarck N.D.

ANSWER—Any attempt to explain this condition on the basis of the facts set forth encounters obstacles somewhere. First a central nervous system lesion such as syringomyelia is not often found in the lower extremities alone and almost never is so sharply defined. In addition the tactile sense is usually retained. The correspondent does not tell of the neurologic findings elsewhere, so it is assumed that they are normal except for the left leg. A spinal cord tumor or a myelitis would produce changes on both sides.

Secondly, although no pulse may be made out in the lower left leg, it is unlikely that the condition is primarily one of arterial disease. Primary arterial disease is usually associated with pain. Early, before the onset of gangrene pain is the principal symptom and may be severe. Edema is not a part of arterial disease.

There is obviously a circulatory disturbance. The history of onset with trauma would suggest the occurrence of a thrombophlebitis at the point of injury. It must then be assumed that the process is slowly ascending in the veins of the left leg. At the time the condition was described it must be assumed that the circulation was severely impaired in most of the leg below the knee.

The objection to this hypothesis is that it does not explain the anesthesia in the leg, and it totally disregards the aphthae and the bleeding gums. It is extremely difficult to connect the mouth condition with the disturbance in the leg in the presence of all the other negative findings. It seems unlikely that the situation represents an avitaminosis in view of the lack of response to vigorous vitamin therapy.

To obtain further information it would be well to have a thoroughgoing neurologic examination if this has not already been done. A microscopic examination of a bit of muscle might reveal the presence of some systemic vascular disease. The adequacy of the circulation in the left leg should be investigated with the histamine flare or by careful observation of the skin temperature. Meanwhile the leg should be treated for thrombophlebitis with rest, elevation and perhaps compression. The use of heparin dicumarol or both should be seriously considered.

PHENYTOIN SODIUM FOR ASTHMA

To the Editor—Will you please comment on the value of phenytoin sodium in the treatment of bronchial asthma?

M.D. Massachusetts

ANSWER—Phenytoin sodium (sodium diphenyl hydantoinate commercially known as Dilantin Sodium) was described in 1937 and 1938 by Merritt and Putnam as a new anticonvulsant. They reported that the drug gave excellent results in the treatment of epilepsy. When large doses were used, toxic effects occurred: nausea and vomiting, nervousness, tremor of the hands, drowsiness, headache, ataxia, hypertrophy of the gums and toxic der-

matitis varying from an erythema to a severe morbilliform rash. Patients who received 0.3 Gm or less daily showed few or no toxic symptoms.

Shulman has reported excellent results in the treatment of 7 asthmatic children. All had severe refractive asthma, with positive cutaneous tests but with indifferent therapeutic results despite the fact that they had been under treatment for at least a year. Phenytoin sodium was given for periods varying from five to twelve months and all other medication was stopped. The initial dosage was $\frac{1}{2}$ grain (0.032 Gm) twice daily. If symptoms persisted the dosage was increased to $\frac{1}{2}$ grain three times daily and some patients received as much as 3 grains (0.2 Gm) a day. Six of the 7 patients were rendered symptom free, although 2 of the children had mild abortive attacks. One patient developed toxic symptoms which cleared rapidly on withdrawal of the drug; this patient was able to resume the treatment with a slightly smaller dose. In 2 cases seasonal nasal and ocular symptoms could not be controlled by the drug. Relief of a concomitant eczema occurred in 2 cases. Shulman notes that, as in epilepsy, the use of phenytoin sodium leads to an improvement in the personalities of some of the children, and he suggests that the drug might be best suited for patients with chronic asthma in whom a psychogenic factor exists. Further studies in this field are necessary but the results are encouraging.

ADMINISTRATION OF MORPHINE

To the Editor—In the Dec 19, 1942 issue page 1349 you published your answer to Major M. Abrams on morphine administration. The remarks on sublingual administration deserve serious reconsideration as they are based on impressions in the older literature that have not been established. In 1928 this question was studied by actually determining quantitatively the morphine unabsorbed from the sublingual space. It was concluded that little if any was absorbed (Davis David and Ayman David. Sublingual Absorption of Drugs. *Morphine Arch Int Med* 41: 231 [Feb] 1928). It is my impression that the effects of sublingual administration of morphine are those of absorption from the gastrointestinal tract after the drug is swallowed. On the other hand I fully agree that morphine is quickly and completely absorbed from the gastrointestinal tract. In my experience when properly administered by mouth the effects may be as rapid as those following subcutaneous administration. For many years now I have recommended the use of a hypodermic tablet completely dissolved in an ounce of water to be followed immediately by a glass or two of water. When the stomach is empty the effects are often experienced within two or three minutes. When given on a full stomach and followed by sufficient water the effects are rapid also. Your statement that the sublingual route protects the morphine from the action of gastric ferments and that morphine is excreted into the stomach are misleading and without foundation (Hatcher R. A. and Davis David. The Excretion of Morphine into the Stomach. *J Pharmacol & Exper Therap* 26: 49 [Aug] 1925). It is important to inform members of the Medical Corps that morphine is not appreciably absorbed from the mucous membrane of the mouth as this procedure will undoubtedly delay its action. It is also important to emphasize that morphine may be quickly absorbed from the gastrointestinal tract if taken in complete solution. The method suggested is a hypodermic tablet completely dissolved in water and then followed by water, to wash it into the circulation.

David Davis M.D. Boston

EXPRESSIONS OF VISUAL ACUITY

To the Editor—Ophthalmologists are accustomed to designate their findings on visual acuity by referring to a standard distance (for instance 20/50, 20/80). On the other hand it seems that in all tests given by the services a standard size letter is used and the examinee has to approach this letter until he is able to read it. Therefore the official designations of visual acuity for the services read 12/20 15/20 and so on. Examiners may have difficulty in comparing these two different kinds of designations. There is a simple way of conversion by dividing the figure one wants to convert into 400. For instance 20/25 of the ophthalmologist's designation equals 16/20 since 400 divided by 25 equals 16. 12/20 of the services' designation equals 20/33 since 400 divided by 12 equals 33.

I hope these remarks will be helpful.

PERSONALITY CHANGES FOLLOWING SUBSTITUTION THERAPY IN PRE- ADOLESCENT EUNUCHOIDISM

JACOB KASANIN, MD

SAN FRANCISCO

A D

LIEUTENANT COLONEL GERSON R BISKIND
MEDICAL CORPS, ARMY OF THE UNITED STATES

The dramatic physical changes resulting from the administration of testosterone and its derivatives to males with hypogonadism have been the subject of many reports since the introduction of this specific therapeutic agent¹. The anatomic and physiologic changes have received special attention, but the descriptions of the physiologic changes have with few exceptions been meager, in general, these factors have been overlooked². It is our purpose in this communication to present in greater detail the changes of personality that occurred following specific treatment in 7 cases of eunuchoidism.

The cases under observation represent moderate to severe types of hypogonadism that have been treated by the subcutaneous implantation of pellets of testosterone or its derivatives. In 3 cases previous therapy in the form of injections of testosterone propionate in oil had been given. Two types of pellets were used. Small pellets of methyl testosterone were prepared by compressing the crystalline material³ in a mold⁴. Approximately 15 pellets representing 150 mg were implanted every ten weeks. Four large pellets, each weighing approximately 200 mg and generally composed of testosterone propionate, were implanted once a year. The effectiveness of therapy was determined by the physical changes, particularly the enlargement of the penis and prostate, the appearance of pubic and axillary hair, the deepening of the voice and enlargement of the neck and the alteration in body contour

with the development of the muscles of the shoulders, arms and thorax. Associated with these changes were a development and increase in libido expressed by masturbation, an interest in women and, whenever possible, by intercourse. The concomitant feeling of well-being and of optimism and the change of attitude to the environment which are expressions of personality modifications that resulted from treatment will be described in greater detail.

The patients themselves have been very helpful in describing minutely the changes in personality following treatment. All had had much ineffective nonspecific treatment of various types before they came to us. They had learned to be quite skeptical and expected very little from any treatment. Thus the element of suggestion is fairly well eliminated. All the patients had become quite introspective since adolescence when at the age of 14 or 15 they discovered that they were different from other boys, and then in time they became convinced that there was very little possibility of any improvement in their condition. The patients were very reticent concerning their pretreatment existence until they saw that the rapid physical response to therapy was of a permanent nature, at which time they gave data previously withheld.

From the Departments of Psychiatry and Pathology Mount Zion Hospital.

Read in part before the California Medical Association Del Monte, Calif. in May 1942.

One must visualize the reaction of a young boy when he realizes that he has undescended testicles or that his testicles are atrophic. These boys in their early childhood were active, healthy, husky children able to compete with or even excel other boys, at adolescence they suddenly discover that they are different from other boys, who make fun of them. Whereas previously their rate of growth was on a par with the normal boys, at adolescence our patients ceased to develop sexually and to mature. The normal boys begin to excel them in sports and social activities and are gradually transformed into young men. Our patients remain adolescent, take on an abnormal body contour, retain a high pitched voice and show no growth of genitals. They doubt then that they are real men. This leads invariably to a great deal of resentment mixed with the feeling of rage and frustration, which is usually repressed, and the only thing evident on the surface is a feeling of bitterness and hostility to the world at large. The most important change effected by successful treatment is a better relationship to the world. All these patients describe in one way or another that they become warm, more affectionate, less hostile, less jealous and not so bitter and that they do not shrink from people any more. They meet men and women on an equal basis, and they are not afraid to compete. Together with this there comes a feeling of growth and security, and the patients state that they "are less jumpy, more firm, more definite, not so irritable". All this will be elaborated in greater detail in the review of the cases.

These patients spend a great amount of energy in solution of the neurotic conflict created by the hypogonadism. Even though the conflict has factual rather than fanciful causes, the influence on the psychic life is the same. An emotional conflict in which the patient is not sure of his sex (and this occurs in many other conditions, including neuroses and schizophrenia) gives rise to a tremendous amount of speculation, indecision and a feeling of hopelessness. As with any other patient whose neurosis is resolved by psychotherapy or analysis, there is a newly gained feeling of freedom after successful treatment. There is a feeling that one can carry out one's own decisions without constant inner struggle and a feeling that one has become a different person. The energy which was previously spent in the solution of the neurotic conflict is now released, and the patient is able to do a good day's work without constant anxiety. This is indicated by the fact that all our patients said that their work takes them much less time and that in the same space of time they do more and better work. This combined with a certain amount of self assurance and even aggressiveness results in their giving up inferior positions and looking for, and finding, more remunerative employment. Several patients were able to go off to relief and obtain independent positions. Other patients were advanced from subordinate to executive positions. All this is described by the patients themselves as "becoming more ambitious." There is less strain, less fatigue, more firmness, less suspiciousness and a growing feeling of security. Together with such changes there comes a feeling of "belonging," of being in unison with the world and a general feeling of well-being. The changes brought about by the treatment are described by the patients in various ways, depending on the educational and intellectual background.

REPORT OF CASES

CASE 1—A B, aged 29, a tall, lanky, asthenic looking man appeared very lethargic, dull and apathetic. He had been a poor scholar and had to repeat the sixth and seventh grades. He was brought up in a broken home, was placed in an orphanage and ran away from school several times. He was involved in minor delinquencies and finally was committed to a school for delinquent boys at the age of 17. However, his behavior was very good after he left the institution. He was able to work as a janitor without returning to a life of crime. The patient stated that he noticed as a boy that his genitals were small, but he always hoped that they would grow. At the age of 15 he became aware that something was radically wrong with him, and that worried him a great deal. The patient began to masturbate at the age of 12. This habit has continued until the present time. His criminal activities coincided with the height of his anxiety about his sex organs. The only way he could prove his masculinity to the other boys was by stealing, hoping that this would be used as evidence of sexual potency. There was no history of homosexual relations. The patient was attracted to girls but never dared to approach them on account of the small size of his genitals. The impression he gave was that of a lethargic, withdrawn, introverted boy with a strong sense of inferiority, to which he reacted at first by criminal behavior and afterward by complete resignation and withdrawal.

Before treatment the following measurements were recorded. His height was 183.7 cm, span 192.5 cm, lower measurement 100 cm. His weight was 66.8 Kg. The penis was 3.5 cm long and 5.5 cm in circumference, the right testicle was 2 cm in diameter and the left testicle was absent. The scrotum was small. The body hair was scant, with a feminine distribution and no beard could be distinguished. The voice was high pitched. The bone age was between 16 and 18 years.

November 4, 1940 a subcutaneous implantation of 4 pellets of testosterone propionate totaling 800 Gm was made.

One year after treatment the pellets were still palpable and effective. The penis measured 6.5 cm in length and 7 cm in circumference. The measurements of the body and the bone age did not change. The voice deepened. Body hair retained a female distribution but became more abundant. The facial hair required shaving every two weeks. The right testicle measured 3 cm in diameter, but the enlargement was mainly in the epididymus.

When the patient returned a year later for examination we were surprised to see a tall, husky, rawboned rangy looking man, self assured and confident. The first thing he did was to remark that he had quit his job and that he was looking for another position. He was better in every way. He liked more people. He was not so tired and felt much stronger. The patient stated that the work of a janitor was not interesting and he was now going to work in the shipyards as a welder. The following changes in his personality were evident. He felt and acted more alert, ambitious and imaginative. He had initiative and was more aggressive and even rebellious. The patient stated that he was more outspoken but he himself is easier to get along with because he has become more firm and honest and does not try to court every one's favor, he is not as cranky and irritable as he used to be. In reference to his sex life the patient stated that he had frequent erections and was going with a girl.

CASE 2—C D, aged 20 was tall and thin, had a very broad chest and large buttocks. Had no facial hair spoke in a high pitched whisper and was shy and reserved. He stated that he came to California only four years before from a farm in the Middle West. He did all kinds of work and was on a National Youth Administration job in the city. For the past six weeks he had been working as an attendant in a hospital. The patient stated that he had known nothing about sex until he was 15. He hoped that his penis would grow but it didn't. At the same time he noticed that instead of a chest he had a bosom and that his hips were becoming very large. He tried intercourse several times but had difficulty getting an erection and had premature ejaculations. Being aware of the small size of his penis he was very shy and kept away from girls. He also avoided boys. He was depressed very quiet and discouraged.

Before treatment the following measurements were recorded. His height was 178.2 cm, span 175.6 cm, lower measurement 94.8 cm. His weight was 87.3 Kg. The penis was 4 cm long and 8 cm in circumference. Each testicle was 3 cm in diameter and held close to the pubic bone. The scrotum was small. The body hair was scant but the pubic hair extended slightly to the umbilicus. The voice was moderately high pitched. There was no beard.

Subcutaneous implantation of 2 pellets of testosterone propionate totaling 400 mg was made. One pellet sloughed out three months later.

Examination ten months later showed no change in the size of the testicles. The penis was 5.6 cm long. The voice had deepened slightly. The facial hair was fuzzy and required shaving once or twice a month. An acneiform eruption was present on the face. There had been a gain in weight to 100 Kg.

When the patient came six months later he stated that he felt much better, and one could notice a decided difference in his appearance. There were greater poise, self assurance and optimism. The patient stated that he had been working all this time in a hospital but now he was leaving it to work in an airport. He had broadened out physically and had gained weight. He was going out with girls. He was quite active sexually, had good erections and was able to have satisfactory intercourse. It bothered him, however, that his penis shrank after intercourse. The patient planned to get married as soon as his job at the airport materialized. He was quite articulate but tried to convey the impression that "he was more sociable, not so bashful and more self confident."

CASE 3—E F, aged 33, was an undertaker and presented a sober, funereal appearance. At the age of 8 years a bilateral orchiopexy had been done, but the testicles failed to grow. For many years various types of glandular therapy had been tried without success, and the typical habitus of preadolescent eunuchoidism developed. After three years or high school

education he worked at odd jobs. For the past thirteen years he had been an undertaker. He had had occasional erections but no seminal discharge. He went with his wife for six years before he married her. They were both very much in love with each other and finally the patient explained his condition to her and stated that he was not able to have intercourse. The girl understood and consented to marry him. They had been married for six months and the wife was still a virgin. Their sexual life consisted largely in mutual masturbation. The patient stated that up to the age of 18 or 20 he was frequently approached by homosexuals. He reacted violently to such attempts, as he had been warned by a physician that such approaches would be made to him.

Before treatment the following measurements were recorded: height 170.6 cm, span 170 cm, lower measurement 90 cm and weight 63.6 Kg. The penis was 2.5 cm long and 5 cm in circumference. The scrotum was very small and appeared bifid with a small mass in each side. The body hair was extremely scant, with a feminine distribution, and facial hair was almost invisible. Bone age studies showed complete fusion of all epiphyses. The basal metabolic rate was minus 26 per cent. The voice was high pitched.

Treatment consisted of the following implantations:

Dec. 23, 1940, 18 pellets of methyl testosterone, total 169.5 mg

Feb. 26, 1941, 4 pellets of testosterone propionate, total 800 mg

March 30, 1942, 2 pellets of testosterone propionate, total 400 mg

Fifteen months after the first implantation the penis measured 5.5 cm. in length and 7.5 cm. in diameter. The voice became deep. There was moderate proliferation of body hair and a scant fuzz appeared on the face. His height and weight remained stationary but his shoulders became heavier and his hips thinner.

When the patient came in April 24, 1942 there was a decided change in his appearance. He was alert, eager, snappy and peppy, his eyes were shining and he was grinning from ear to ear. His funeral appearance was gone and he was wearing bright sport clothes. The patient stated that he felt "swell", his work was going along very satisfactorily and he was getting a promotion. He stressed the fact that he had changed physically a great deal. Ten days after the implantation he began to have emissions of seminal fluid. He had definitely penetrated his wife and both he and she enjoy intercourse. She now has definite orgasms. His wife is more cheerful and the treatment has brought them together. The patient stated that he is a different person, small things do not bother him, he is not so jumpy, he is less irritable, he thinks differently, he is more secure and he is able to make definite plans and carry them out. The patient discussed his plans of enlarging his business which seemed to be quite realistic and which he has been able to follow through since the interview.

CASE 4—G. H., aged 40, an alert, eager, active business man, was extremely ingratiating and almost too eager to cooperate. He stated that he had had undescended testicles and that at the age of 13 an orchiopexy was unsuccessful; no testicular tissue was demonstrable. Six years later he had an unsuccessful transplantation of testicles from a convict. He was always aware of the small size of his penis and the atrophic testicles, and he reacted to it by being very active, aggressive and positive. He worked in all sorts of occupations, including that of ship fitter and sailor, and was very active in various sports. He was very intelligent and graduated from high school in three and one-half years. He graduated from a business school of one of the local universities and immediately after this was given a position, first as a salesman, then rapidly promoted to a responsible executive position. At the age of 30 he began to go out with a girl and married her when he was 33. Before he was married he had explained to his future wife his difficulty, but she loved him so much that it did not matter. They had occasional intercourse with no seminal discharge.

Before treatment the following measurements were recorded: height 181 cm, span 186 cm, lower measurement 106 cm, and weight 94.7 Kg. The hair on the face was scant and downy, body hair was almost absent and the sparse pubic hair had

a feminine distribution. The voice was high pitched. The skin of the face was soft and finely wrinkled. The penis was 4 cm long and 6 cm in circumference. In the erect state it was 7 cm long. The scrotum was very shrunken and appeared bifid, and no tissue was palpable in it. On rectal examination the prostate and seminal vesicles were not palpable. The basal metabolic rate was determined twice and was minus 23 per cent and minus 19 per cent.

Five separate implants of methyl testosterone pellets were given between March 1940 and May 1941, making a total of 740.5 mg. An average of 17 pellets were implanted each time. Four large pellets of testosterone propionate totaling 800 mg were given in May 1941. They were effective until June 1942, when 3 additional pellets were implanted.

After two years of treatment the penis measured 7 cm in length and 7.2 cm in diameter. The prostate was palpable. The pubic hair became heavier but remained feminine in distribution. The sallow, fawn color of the skin of the face disappeared and the characteristic facial periorbital wrinkles became much less evident. The hips became smaller and the shoulders enlarged. The voice was deep and well modulated.

When the patient came in following treatment he described the changes as follows. His drive for success has been more intense and he has had more financial success than ever before in his business. He has less fatigue and more energy. He has much more sex drive. He was very proud of the fact that hair had begun to grow all over his body and that he had emissions of seminal fluid. Intercourse was complete and pleasurable. The patient stated that he was more affectionate, that he did not try to please people as much as he had before and that he liked people more. He was less jittery and not so insecure, as he expressed in a jubilant exclamation, "I am part of the world, I am normal."

CASE 5—I. J., aged 27, was tall, asthenic, pale and beardless and looked like a boy of 18. The patient stated that he had come from a large family, had gone to high school and had studied for two years in a midwestern university. At the age of 20 he came to San Francisco and began to work in a drugstore. He had had mumps in childhood but did not remember whether that illness had been complicated by orchitis. He had had occasional erections but there had been no emissions. He was treated with testosterone propionate for eunuchoidism by a physician until referred for implantation therapy. The patient stated that the treatment produced the following changes. He had had a high pitched voice which now was normal. His attitude in conversation was more free. He showed a greater sense of humor. He was more aggressive and recently he was promoted to the job of an executive. Before treatment he could not take charge of people. His orders were not carried out. He was afraid to give orders for fear people would laugh at his high pitched voice. Now his voice was more resonant. He could assume a definite tone of authority and he talked more slowly and was more deliberate. His associates took orders from him because he was more consistent and less arbitrary. Before this he was always in difficulties and disputes with the other employees, and for these reasons he was not promoted. He could meet girls now and they did not frighten him. Recently he was in a girl's home and was told by the family that whereas a year ago he would read a book when he came to see the girl at present he was really interested in her and wanted to be with her alone. He had regular erections and occasional emissions. Prior to the change in his voice he had to be very careful in choosing his friends for fear they would try to make homosexual approaches to him, now he was not afraid of that. Since he had been under treatment he felt confident that he could become a real man.

Before treatment the patient was tall, thin, long legged and beardless and had a high pitched voice. The complexion was sallow. Pubic hair was slight in amount and axillary hair was negligible. The penis was small, the left testicle was extremely atrophied and the right testicle was much smaller than normal. The prostate and seminal vesicles were not palpable. His weight was 56.8 Kg, the height was 179 cm, the lower measurement 96 cm and the span 182 cm. He received a total of fifty-nine injections of 25 mg of testosterone propionate in oil, three injections a week up to March 1940.

Implants of methyl testosterone pellets were started in April 1940, a total of 511 mg, distributed in four implantations, was given until December 1940.

The large pellets of testosterone propionate were implanted in December 1940, but the original 4 sloughed out and 3 additional pellets were implanted in March 1941. These also were extruded from the wound and an additional 4 large pellets totaling 800 mg were implanted in July 1941. These proved entirely satisfactory and effective through May 1942.

A recent examination showed that there had been no change in major body measurements but an increase in weight had occurred. The penis more than doubled in size and measured 9 cm in length and 8.5 cm in circumference. His voice was deep. His neck and shoulders had increased in size. The pubic hair was heavier and was growing toward the umbilicus.

CASE 6—K. L., aged 19, a tall blond boy, spoke intelligently and freely. He stated that he had one undeveloped descended testicle and one undescended testicle. Two attempts at orchiopexy had failed to place the undescended testicle in the scrotum. He was brought for treatment by his father, who stated that the patient had failed to mature in that his play activities were with children five and six years his junior, his mannerisms were of the fussy feminine type, and his beard and genitals were not developed. The patient had no sexual desire, he had had occasional erections but no seminal emissions. He was very bashful and afraid of girls. He was always somewhat nervous, jittery and restless. When he was small, things used to "bother" him at home, apparently there was a great deal of discord in the family. Since adolescence he had been in a constant state of anxiety. The boys used to tease him and talked about the fact that he had no testicles and laughed at him because he had a small penis. Before implantation therapy was started he had had sixteen injections of testosterone propionate, 10 mg in oil, given by the referring physician.

The patient was immature and boyish, appearing younger than the stated age. His height was 168 cm, the span 171 cm and the lower measurement 87.5 cm. His weight was 68 Kg. The voice was high pitched and the body hair scant. The penis was 6 cm long. The scrotum was small, shriveled and limited to the right side and contained a pea sized bit of tissue. The prostate was barely palpable. His bone age was placed at 13 years. The basal metabolic rate was minus 16 per cent.

Implants of methyl testosterone pellets were started in November 1939, and up to December 1940 he had had five implantations averaging 18 pellets each. The total amount of methyl testosterone used was 643.8 mg.

Four large pellets, each 200 mg, were implanted in December 1940, but several sloughed out so that an additional 4 similar pellets were implanted in September 1941. These have been effective for almost one year.

The physical changes resulting from treatment were an increase in body and facial hair, a deepening of the voice and development of an acneiform eruption on the face and shoulders. The penis measured 10 cm in length and 9.5 cm in diameter. The scrotum enlarged. He grew 7 cm in height.

Following treatment the patient noticed that there had been a decided change in his libido. He started to go out with girls. He developed sexual desire, which he has desired to control until marriage. He began to go to dances and enjoyed going with girls. He was more eager now to succeed. He was not satisfied with his job in a gas company and intends to go into the army. He had occasional nocturnal emissions and frequently dreamed of girls, occasionally he had to resort to masturbation. His anxiety was greatly diminished. He was more calm and more definite and self assured.

CASE 7—M. N., aged 21, a student in one of the local universities, was referred to the clinic for implantation therapy for typical preadolescent eunuchoidism. The patient was a tall, good looking, attractive, blond boy with a pleasant engaging smile, he was very intelligent and obviously well brought up. As a little boy he could "lick" other boys in school, but after the age of 12 he began to lose out, and instead of being the leader in his class the other boys began to pass him up. They became huskier and taller and better athletes than he was, whereas previously the patient was much stronger than they were. The family did not worry about it, since both

his father and mother were quite late in maturing. Prior to the specific androgenic treatment the patient had had no erections and no emissions. The patient stated that on several occasions he had been approached by homosexuals but repulsed their advances. He knew about homosexuality from other boys in his fraternity.

Physical examination in September 1941 revealed the following measurements: height 178 cm, span 178 cm, lower measurement 92.5 cm and weight 62 Kg. The penis was 10 cm long and 9.7 cm in circumference. The scrotum was fairly loose and wrinkled and contained a mass 2 cm in diameter on the right side, nothing was palpable on the left side. The pubic hair was fairly abundant but of feminine distribution. Axillary hair was scant and facial and body hair was absent. The bone age was less than 14 years. The basal metabolic rate was plus 10 per cent.

In the year before the examination described he had received two or three injections a week of testosterone propionate, 23 mg in oil, for approximately eight months, terminating four months before the examination.

Three large pellets of testosterone propionate were implanted subcutaneously in September 1941.

Examination in February 1942 showed no essential change in the foregoing measurements. The voice was slightly deeper and better modulated. The erections and nocturnal emissions occurred as frequently as they had during the testosterone propionate injections.

The patient stated that following the specific therapy he was much better and quite different. He developed an interest in girls, his libido increased and he was disturbed occasionally. He left the university and obtained a position in one of the shipyards. He was more mature and stable, had greater interest in his work and was planning to enter aviation. He was going steadily with a girl whom he planned to marry within a short time. The patient stated that he was more mature and better balanced, was able to save money and was less of a kid.

COMMENT

In reviewing these cases, one finds that there are two ways in which these patients reacted to their sexual inferiority. The more simple, less complex persons with limited background and intelligence reacted to their eunuchoidism by submissiveness and withdrawal. They became misanthropic, detached themselves from people, shying from the company of women as well as avoiding association with men. In some instances there was a defensive attempt at pronounced aggressivity, with efforts to prove to the other boys that they were regular fellows. They became leaders in their neighborhood gangs, one followed a criminal career. These attempts at compensation were usually quite sporadic and lasted only a short time. They carried on more or less routine jobs with inferior salaries, not daring to ask for a raise in pay. They did not go out with girls for fear that their inferiority would be discovered.

The second group, with more intelligence and better backgrounds reacted to their feeling of inferiority resulting from the hypogonadism by overcompensation. Thus our executive (case 4) from the very beginning became a very active, extroverted person, a leader in activities and sports. Nonetheless he was in constant dread that his condition might be discovered. At the same time there were definite evidences of psychosexual maturity with capacity to care for another person of the opposite sex. Thus two of our patients had married not for the sake of appearances but of genuine love for their wives. This latter point is important to bear in mind in connection with the question of homosexuality, which will be discussed later.

In general then the reactions of these patients were either of extreme submissiveness or of aggressivity and arrogance. Frequently these were intermingled

with feelings of jealousy and hostility. These patients were constantly on guard, vigilant and never at ease.

Following successful treatment there was a decided change in the aforementioned attitude with a feeling of poise and security. The patients were no longer on guard lest some one take advantage of them, lest they be made completely feminine. In regard to the married patients, as the treatment gave them the capacity to carry out normal sexual relations there was a noticeable increase in the sense of security and feeling of fulfillment, felt both by the patients and by their wives.

It is significant that in spite of the hypogonadism and attendant feminine build of these patients none of them became homosexual. As stated in the histories homosexual approaches and attempts at seduction were made, but the patients reacted with repugnance and disgust, and none of them recalled having had any sexual experience with men after adolescence—none beyond the usual experimental sex play in childhood when our patients were normal, husky children. As previously mentioned, 2 of the 7 patients married and 1 had definite plans of marrying, and though the element of keeping up appearances was dominant they appeared to be genuinely in love.

Thus, in this group of patients at least, there was no evidence that hypogonadism was in any way associated with homosexuality. Comparing this group with a similar group of 15 homosexuals who came to us in connection with the selective service, we have come to the following conclusions. All the homosexual boys had large, well developed sexual organs with well developed testicles. Nearly all of these homosexual men had strong sex drives, as evidenced by frequent erections, nocturnal emissions and fantasies—all, however, misdirected to their own sex. None of them had any desire for women, but all of them had very strong sexual drives with libido directed to other men either passively or actively. Comparing these two groups, one cannot avoid a conclusion that there must be psychologic rather than physiologic factors which tend to direct men into homosexuality.

SUMMARY AND CONCLUSIONS

1 Psychologic changes took place in 7 patients with preadolescent eunuchoidism treated by implantations of testosterone derivatives.

2 Anatomic and physiologic changes that resulted from specific androgenic therapy did not differ from those described in the literature.

3 The eunuchoid patients had reacted to their defect either by strong passivity and submission, with sporadic attempts at overcompensation as expressed in delinquent behavior, or else by overcompensation in becoming very aggressive, domineering and overactive.

4 The psychologic changes following successful therapy consisted in gaining a feeling of security, greater emotional stability and a feeling of belonging, with the disappearance of a constant state of vigilance, suspiciousness, pettiness, fussiness, jitteriness and a more or less constant state of anxiety. The improvement can be compared to a successful therapeutic result in a typical neurotic state.

5 In our series eunuchoidism did not preclude a normal feeling of affection and love for members of the opposite sex.

6 A comparison with a control group of 15 homosexual men indicates that psychologic rather than physiologic factors are responsible for the development of homosexuality.

TREATMENT OF EDEMA OF RENAL ORIGIN

REPORT OF TWELVE CASES

HENRY J. LEHNHOFF JR., M.D.

Fellow in Medicine Mayo Foundation

AND

MELVIN W. BINGER, M.D.

ROCHESTER, MINN.

The patient who suffers from nephrosis or from the nephrotic state of chronic glomerulonephritis has as his predominant symptom edema, which is characteristic of this clinical entity. Not only is it the main symptom, but it is the outstanding feature of his illness, which keeps him an invalid and prevents his maintaining a normal or nearly normal economic and social existence. When the nephrotic features of glomerulonephritis predominate, hypertension, with its accompanying symptoms due to vascular changes in brain, heart and kidneys, is rarely present. Renal function is usually good and there usually is no retention of nitrogenous matter in the blood. There is little or no anemia. In other words, except for the generalized edema and the symptoms secondary to it the patient usually feels well, and if the edema was absent he could live a fairly unrestricted life. To attain such an end and to rehabilitate patients who have been so incapacitated we are presenting an outline of therapy which has proved satisfactory.

Without going into detail, the edema of nephrosis is the result of retention of water and the accumulation of an excess of sodium chloride in the tissues. These changes are brought about by loss of protein in the urine or lack of protein in the patient's diet or, occasionally, both. This results in a decrease in the concentration of serum protein, a subsequent decrease in colloidal osmotic pressure of the serum and a tendency to edema formation and the retention of salt in the tissues of the body.

The following significant laboratory findings are present: albuminuria, a decrease in the concentration of plasma protein and an increase in the amount of sodium chloride in the plasma and tissues. The colloidal osmotic pressure of the plasma (normal, 214 mm of mercury or 360 mm of water) is decreased. Anemia, definite hematuria and pronounced retention of nitrogenous waste products usually are absent. Hypercholesteremia is present and the basal metabolic rate usually is low. Vascular changes are rare and occur only in cases in which there is extensive glomerular involvement. There is a decrease in plasma volume.¹

Since the renal lesion cannot be attacked directly, some means of eliminating the sodium chloride and water from the body through the urinary tract must be employed. The serum protein must be augmented. The intake of water and salt must be restricted. Although modified for each case, an outline of treatment based on the clinicochemical factors just mentioned has been found to be most efficacious. It consists of dietetic and diuretic measures which restore the physico-electrolytic balance in the body.

From the Division of Medicine Mayo Clinic.

DIET

The patient is instructed to use a diet containing 100 to 125 Gm of protein daily. It is salt free except for the natural salt contained in the food and contains between 1,000 and 1,500 cc of fluid. If his edema free weight is normal, the diet furnishes approximately 2,000 calories. It may be supplemented by any reliable vitamin concentrate. An adequate, healthful diet is as essential in the treatment of this disease as in that of any chronic illness.

DIURETICS

The diuretic agents can be divided into two groups: (1) those which have a direct action on the kidneys,

as diuretic agents. The manner of their use will be described in detail in the ensuing reports of cases. Their advantage is in their low toxicity, desired diuretic action and ease of administration. Mercurial diuretics, although usually efficacious, are generally not needed when the diuretic program is established.

The use of acacia in the treatment of nephrotic edema is still considered by some to be a rather heroic measure, to be employed only under strenuous circumstances. Goudsmit and Binger⁴ recently reported that it was a reliable and reasonably safe procedure.

The clinical and laboratory observations pertinent to 10 of the patients so treated maintain a certain uniform-

such as mercurial preparations, potassium and ammonium salts, caffeine derivatives, concentrated solutions of dextrose and (2) those which act by affecting the colloidal osmotic pressure of the blood such as whole blood or plasma, which should be administered by transfusion, and acacia, which should be administered intravenously. The latter produce diuresis by increasing plasma volume and by promoting a saline diuresis as well as by raising the colloidal osmotic pressure.² In previous communications Keith and Binger³ described the advantages of potassium salts (potassium nitrate)

and are therefore recorded in tables 1 and 2. In all cases the diet yielded 2,000 calories a day and contained from 100 to 125 Gm of protein and from 800 to 1,200 cc of fluid. No salt was added to the food in preparation. Each patient received 9 Gm of potassium nitrate daily and was given iron and vitamin concentrates as needed.

Vascular changes appeared only in case 7, as evidenced by the blood pressure, which varied over twenty-four hours between 180 and 132 mm systolic and 120 and 70 mm diastolic, together with minimal narrowing of the retinal arterioles.

⁴ Goudsmit Arnoldus Jr. and Binger M. W. Treatment of Nephrotic Edema. *J. A. M. A.* 114: 2515-2517 (June 29) 1940. Acacia in the Treatment of the Nephrotic Syndrome. *Arch. Int. Med.* 65: 1252-1281 (Dec.) 1940.

Each patient received a minimum of three intravenous injections of 500 cc of a 6 per cent solution of pure acacia in a 0.06 per cent solution of sodium chloride at intervals of from one to two days. In some cases more acacia was required to obtain the desired effect. The concentration of acacia in the serum was determined one day after the last injection. If the concentration of acacia was 2 Gm or more per hundred cubic centimeters of serum, further treatment with acacia was not employed. Otherwise the administration of acacia was continued not only until the patient was free from edema but until the concentration of acacia in the serum reached a satisfactory level. A few patients suffered slight reactions, consisting of mild headache, backache or feeling of constriction in the thorax. All were relieved by slowing the rate of flow of acacia into the vein or by administration of small doses of ephedrine or epinephrine.

Careful examination was carried out in all cases for active foci of infection. Several patients had infected teeth extracted or underwent tonsillectomy during their hospitalization. While this report is not directly concerned with the bacteriologic aspect of nephritis, it is known that streptococcal infections can be serious etiologic factors in acute glomerulonephritis and can precipitate acute exacerbations of chronic glomerulonephritis. Focal infection should be eradicated in these cases.

When ready for dismissal from the hospital each patient was instructed about a proper diet and was advised to follow this diet and to take potassium nitrate until advised otherwise by the physician in his home locality. The diets of those whose nutritional state was poor were augmented by vitamin concentrates and iron.

Patients 2 and 7 did not have edema at the time of treatment. These patients were given "prophylactic" treatment with acacia in view of a long history of recurrent edema. Patient 2 had had edema for three years and patient 7 for eight years. It was deemed advisable to administer acacia in the hope that it would increase the colloidal osmotic pressure of the serum and help prevent subsequent edema. At the time of this writing such recurrence has not been reported in either case. One patient (6) who had received acacia two years earlier still had minute traces of it in the blood.

Those patients whose subsequent course has been recorded as "fair" required a second series of injections of acacia after dismissal from the hospital. For example, patient 4 required acacia four months later, patient 6 six months later and patient 8 eleven days later.

Cases 11 and 12, because of the therapeutic problems they presented, are reported in detail.

REPORT OF CASE

CASE 11—An electric foreman aged 39 registered at the clinic complaining of peripheral edema of six months' duration. It had followed a sore throat which had been present for a few days. Previous to this illness he had been quite well and had passed an insurance examination one month before its onset. With the discovery of albuminuria, hypertension and erythrocyturia, he had been placed in bed on a diet low in salt and protein, and a diuretic regimen had been instituted. Nevertheless, orthopnea had developed, he had become more and more dyspneic and the edema of the lower extremities had progressed to massive proportions.

The patient, who was pallid, was well developed. Moist rales were present at the bases of both lungs. The transverse cardiac diameter was 120 cm. The aortic second sound was accentuated. The systolic blood pressure was 200 mm of mercury and the diastolic pressure was 118 mm. There was

definite pitting edema of ankles and legs but no ascites. Examination of the ocular fundi revealed sclerosis, grade 1, of the chronic hypertensive type and widespread retinitis with cotton-wool patches and retinal hemorrhages. The significant laboratory findings are listed in table 1.

A diagnosis of chronic glomerulonephritis with nephrotic features and superimposed diffuse arteriolar disease with hypertension, grade 3, and myocardial failure was made. The patient was given a salt free diet that furnished 2,000 calories. The daily diet contained 100 Gm of protein. Potassium nitrate was administered three times a day in doses of 45 grains (3 Gm). Sodium bicarbonate was administered four times a day in doses of 10 grains (0.65 Gm). Phenobarbital was administered three times a day in doses of $\frac{1}{2}$ grain (0.032 Gm) in addition, $1\frac{1}{2}$ grains (0.1 Gm) of this drug was administered at bedtime. A total dose of 12 cat units of digitalis was administered in four days and 1 cat unit of the drug was administered daily thereafter. Acacia was administered on alternate days.

In the intervening days the patient was given 2 cc of valyrgan for a total of four doses. During that time he lost 28½ pounds (13 Kg) of fluid (fig 1) and became free from

Fig 1—Response to the diuretic measures. Acacia played a role supplemental to digitalis, salyrgan and potassium nitrate; its usefulness is indicated by the massive urinary output of the seventh and twelfth days.

edema, orthopnea and dyspnea, and his general condition improved materially. He was dismissed from the hospital two weeks after admission with instructions to continue the diet and maintenance doses of digitalis and potassium nitrate. His blood pressure did not change as a result of this treatment.

This case differs from the first 10 presented in that nephrosis was complicated by vascular disease and cardiac insufficiency. The treatment of the two components of the illness was compatible, as evidenced by the successful termination after treatment in the hospital. The patient's prognosis is much more guarded than one of uncomplicated nephrosis. We present this problem as one in which treatment with acacia played a supplemental, yet important and effective, role in combating edema, the cause of which was cardiac as well as renal. However, we would not advocate treatment with acacia unless the concentration of protein in the serum is lowered and is considered an adequate cause of the edema.

CASE 12—A man aged 33, who registered at the clinic in January 1940 had been well until September 1939, except for an occasional attack of sore throat. Four months prior to his registration at the clinic, edema of the legs had developed. His physician had made a diagnosis of nephritis and had placed him on a diet low in salt, protein and fluid. Nevertheless the

patient's vision had become blurred, the edema had increased and the systolic blood pressure had increased to more than 160 mm of mercury.

When the patient was examined at the clinic, bilateral hydrothorax, ascites and massive edema of the sacrum, scrotum and lower extremities were present. He was orthopneic and vomited frequently. The blood pressure was 150 mm systolic and 116 mm diastolic. Examination of the ocular fundi gave negative results. The patient weighed 200 pounds (91 Kg) and his height was 73 inches (185 cm). The significant laboratory findings are included in table 1.

The patient was placed on a diet which yielded 2,000 calories, the diet contained 100 Gm of protein, was free of salt and included 800 cc of fluid daily. Nine Gm of potassium nitrate was administered daily. He received three infusions of a 6 per cent solution of acacia in a 0.06 per cent solution of sodium chloride on three successive days. During the next fifteen days he was given intravenous injections of 500 cc of a 20 per cent solution of dextrose in distilled water daily. In this interval he lost 20 pounds (9 Kg). He then received four more daily infusions of acacia, and six doses of 10 cc of salyrgan.

Fig. 2—Effect of acacia on excretion of salt and urinary output of the nephrotic patient. Definite saline diuresis after each injection or series of injections of acacia may be noted. There is a concomitant increase in urinary output.

were administered intravenously in twelve days. On this regimen he lost 12 pounds (5.4 Kg). By this time he had recovered his appetite and the dyspnea had decreased. He was comfortable except for an attack of acute otitis media, which lasted one week but responded well to chemotherapy. Because of a low basal metabolic rate he was given 1 grain (0.065 Gm) of desiccated thyroid daily. Before his dismissal from the hospital the basal metabolic rate had risen to -5 . After fifty-eight days in the hospital he had lost 53 pounds (24 Kg). He left the hospital after seventy-four days, at which time he weighed 145 pounds (66 Kg), or 55 pounds (25 Kg) less than on admission. Edema was absent. During the course of treatment he was given a total of 330 Gm of acacia in eleven infusions of 500 cc of a 6 per cent solution in a 0.06 per cent solution of sodium chloride with no ill results whatever. He is the first patient at the Mayo Clinic to receive such a large quantity of acacia.

Since the patient's dismissal from the hospital in March 1940 he has remained free from edema on a regimen of 6 Gm of potassium nitrate daily and a diet low in fluids, free of salt

and high in protein. The concentration of urea in the blood has remained at about 80 mg per hundred cubic centimeters. On fairly limited activity he has felt extremely well.

Fig. 3—Body contour before treatment. a profile view b front view.

Fig. 4—Body contour after treatment and lapse of twenty months. a profile view b front view.

The so called salt free diet contained 18 Gm of salt per day. From this and from the γ -globulin solution the patient received a total of 1662 Gm of sodium chloride. Daily analyses of the urine for total excretion of salt were made and the output of sodium chloride during his hospitalization was 389.5 Gm. This large negative balance of sodium chloride is striking evidence that the retention of salt is a powerful factor in the production of nephrotic edema. The effect of γ -globulin on the excretion of salt may be seen in figure 2. Following each administration of γ -globulin there was a pronounced increase of sodium chloride in the urine.

Thus, γ -globulin combats edema by its twofold action, namely mobilization of sodium chloride and reinforcement of the serum protein in maintaining the colloidal osmotic pressure. At the beginning of treatment the colloidal osmotic pressure was 117 mm as compared to normal of 360. Unfortunately the osmotic pressure was not determined at the conclusion of treatment. This case is described to emphasize the importance of retention of salt as well as a low serum protein in the production of edema and to demonstrate the effect of γ -globulin in combating these two factors. The value of administration of potassium salts, hypertonic solution of dextrose and salyrgan also is demonstrated. The concentration of proteins in the plasma decreased temporarily following treatment with acacia, this is probably a dilution phenomenon. The albumin globulin ratio changed from 1:12 before treatment to the normal ratio of 1:4 after treatment.

The patient returned to the clinic on Sept. 22, 1941 for further examination. By comparison of figure 3 with figure 4 it may be seen how well the edema was controlled. Except for infected tonsils and blood pressure of 136 mm systolic and 96 mm diastolic, abnormal physical findings were absent. The significant laboratory findings at various intervals are listed in table 3. Of particular interest is the normal level to which the serum protein had risen in spite of persistent albuminuria. The patient weighed 151 pounds (68.5 Kg) as compared to 146 pounds (66.2 Kg) at the time of his dismissal from the clinic twenty months earlier. The concentration of hemoglobin had risen from 127 Gm to 138 Gm per hundred cubic centimeters of blood.

The patient underwent an uneventful tonsillectomy and returned home. He was advised to continue the regimen of potassium nitrate, iron, diet and minimal activity.

COMMENT

These cases are not reported as a series the volume of which is evidence for efficacy of the form of treatment we have described but as a description of the type of case for which acacia is beneficial and the rationale for its use.

Pirogoff—The Crimean War produced another of the really great army surgeons of history, Nicolai Ivanovitch Pirogoff (1810-1881), who was in charge of the treatment of Russian troops in the siege of Sevastopol, which lasted for fourteen months. The conditions under which he had to work were appalling, and the number of men who died as a result of erysipelas, pyemia, hospital gangrene and purulent edema was so high that Pirogoff defined war as "a traumatic epidemic." Almost unaided he toiled at his great task, striving to improve conditions and making many sound recommendations to combat the prevailing sepsis. Through the influence of the Grand Duchess Helena Pavlovna he was able to introduce female nursing for the Russian soldiers at the time when Florence Nightingale was providing a similar organization for the British army. Pirogoff was a firm believer in the importance of early surgical treatment and was one of the first to adopt all the more recent advances of surgery, as is shown by his use of ether anesthesia in 1847 only a few months after this was first advocated by Bigelow, and of plaster of paris bandages in 1854, two years after Mathysen's first description of this technique—Trueta, Joseph. *The Principles and Practice of War Surgery*, St. Louis, C. V. Mosby Company, 1943.

ACUTE BACILLARY DYSENTERY (FLEXNER)

TREATMENT WITH SULFAGUANIDINE AND SUCCINYL-SULFATHIAZOLE

The control of acute bacillary dysentery is becoming increasingly important because of the presence of troops in tropical regions where this disease is common and also because of the poor housing and sanitary conditions which inevitably result from the mass shifting of civilian populations. During the past year numerous reports of the high incidence of this disease have come from the nations long at war, namely, China, Russia, Japan, Germany and Italy.

Uniformly favorable clinical results concerning the value of sulfaguanidine in the treatment of bacillary dysentery have been reported¹. There are, however, few published reports of the use of the newer sulfonamide compound succinylsulfathiazole in the treatment of this disease. This drug was first synthesized in 1939 by Miller, Rock and Moore² and has been reported by Poth and Knotts and others³ to have striking bacteriostatic action against the usual intestinal flora of man and also to be effective against strains of Shiga, Sonne and Flexner dysentery bacilli. Experience with the use of succinylsulfathiazole in the management of acute outbreaks of dysentery has been limited to a few cases occurring in widely separated parts of this country⁴. Our purpose in this communication is to report the effects of these two drugs in an epidemic of bacillary dysentery (Flexner) which occurred in Eloise Hospital and Infirmary during the summer of 1942.

EPIDEMIOLOGY

Starting late in July 1942 an increase in the incidence of diarrhea was noted at this hospital and within a short time five deaths had occurred among 32 patients with diarrhea. It was recognized that an epidemic of dysentery was occurring and that the organism was sufficiently virulent to produce a high case fatality rate. Therefore the Michigan State Department of Health was requested to give aid in its control.

In the three divisions of the institution, psychopathic hospital, general hospital and infirmary, there were at the time of the outbreak 8,000 inmates and 1,800 employees. The patients are housed in fourteen buildings, each having a separate kitchen but a common supply of food, milk and water.

Chart 1—The distribution of cases by date of onset indicating occurrence of suspected and proved cases.

It was found that the outbreak began in two wards for chronically ill patients in one of the buildings which at the time had a patient census of 2,200. The first few patients in whom the diagnosis of bacillary dysentery (Flexner) was established were transferred to the acute general hospital building. Three patients in the general hospital developed the disease and in each case the infection could be readily explained by contact with these proved cases. In order to prevent additional secondary cases an isolation ward was established in a building which was closed at the time, and all patients at the institution who developed diarrhea were immediately moved to this building. Complete isolation was effected and no further secondary cases occurred. With the exception of two attendants, both of whom cared for patients ill with the disease, no cases were found among the hospital personnel. The distribution of cases by dates of onset is shown graphically in chart 1.

The fact that most of the cases occurred in one building and that the outbreak did not have the explosive character of milk or water borne outbreaks indicated quite definitely that food was the source of the infection. This evidence, coupled with the fact that cases developed in widely separated wards of the same building, and that hospital personnel who ate in a separate kitchen were not affected, indicated that the infection had its origin in the main kitchen, where food was prepared only for patients in this building.

To break the chain of infection and stop the epidemic, general control measures were immediately established and a search was made for a carrier or carriers among the food handlers employed in that building. This necessitated taking cultures of the stools from 328 individuals and of these, two inmates who served food in the patients' kitchen were found to have *Bacterium flexneri* organisms in their stools. That these men were the source of the original infection was never proved. Although neither was treated many subsequent stool specimens, including swabs taken directly from the rectal mucosa on three occasions, were negative. One of these men was admitted to the institution two weeks prior to the outbreak and gave a history of chronic vague abdominal pain.

For the purpose of completeness a survey was made to determine whether or not the water supply was safe. Investigation showed that the plumbing was protected by vacuum breakers, there were no submerged outlets and no cross connections were discovered. The milk supply was also investigated as a possible source of infection and found to be satisfactory.

METHOD OF STUDY

On admission to the isolation ward a complete blood count and urinalysis was done in each patient. Cultures of stools were taken daily by means of accepted bacteriologic and serologic methods. A total of 86 patients were isolated for observation during the epidemic and in 26 cases the diagnosis was proved by stool cultures. In 2 additional cases there were negative stool cultures but these were considered "probable cases." One patient had bloody diarrhea and a high temperature and died early in the epidemic in a ward where several positive cases later developed. The other had the characteristic symptoms of the disease and subsequently developed a high serum agglutination titer against the organisms known to have caused the outbreak. Repeated stool cultures were obtained from all positive cases for from six to eight weeks after release from isolation. When the diagnosis was suspected but the organisms could not be demonstrated in the stools, serum agglutination tests were done against *Bacterium flexneri* organisms isolated from the stools of other patients of this epidemic.

Treatment consisted in routine administration of camphorated tincture of opium and bismuth subcarbonate, and when indicated dehydration was controlled by parenteral fluids. One group of 12 patients was given sulfaguanidine, another group of 24 patients was given succinylsulfathiazole. In most cases these drugs were started on the first or second day of the disease, but occasionally not until the third day of illness. With

Chart 2—A comparison of the clinical results in untreated, sulfaguanidine treated and succinylsulfathiazole treated cases. The symbol O indicates no fever or diarrhea. The question mark indicates inadequate data.

few exceptions the dosage of sulfaguanidine was 0.1 Gm per kilogram of body weight initially and 0.3 Gm per kilogram daily divided into six equal parts. The

5 Succinylsulfathiazole is marketed under the trade name of sulfasuxidine and is manufactured by Sharpe and Dohme Incorporated Philadelphia who supplied the drug used in this study.

dosage of succinylsulfathiazole was 0.25 Gm per kilogram of body weight initially and 0.25 Gm per kilogram daily divided into six equal parts given every four hours. The duration of sulfonamide therapy varied from two to fourteen days, most patients were treated for six days.

Chart 3—The development of a carrier state in a patient untreated for sixteen days later cured with succinylsulfathiazole.

On alternate days during sulfonamide therapy complete urinalyses, determinations of hemoglobin, white blood cell counts and sulfonamide blood concentrations by means of the method of Bratton and Marshall⁶ were obtained. Values for succinylsulfathiazole were expressed as "free" sulfathiazole and as total sulfonamide.

CLINICAL RESULTS

In this analysis of the clinical results of treatment discussion will be limited to the 26 proved and the 2 probable cases of acute bacillary dysentery. These cases are divided into three groups: the first group, 6 patients, received no sulfonamide therapy; the second group, 10 patients, were treated with sulfaguanidine; the third group, 14 patients, were treated with succinylsulfathiazole.⁷

Except for the first few patients the day of onset of symptoms could be established with considerable accuracy because all patients were under constant observation by trained hospital personnel who had been instructed to report the occurrence of diarrhea in any inmate. This permitted the isolation and institution of chemotherapy early in the course of the disease. The clinical results are summarized in chart 2.

Group 1 (untreated). There were 6 patients who received no sulfonamide drug and of these 5 were proven cases, whereas 1 was considered a probable case. There were four deaths in this group and autopsies were performed in 2 of these. In both cases throughout the descending colon and rectum there was severe hyperemia, multiple petechial hemorrhages and shallow 1-2 mm ulcerations. *Bacterium flexneri* organisms were cultured from the ulcers in both cases.

Of the 2 patients who recovered, 1 remained febrile for six days and had a nonbloody diarrhea for three days. The stool cultures remained positive through the fourth day of the disease and then became persistently negative during a period of four weeks. The

other patient (S S, chart 3) was a white man aged 50 with a fractured humerus but otherwise in good physical condition. On the day of onset of dysentery his temperature rose to 104.8 F (rectal) and he had seven watery stools. The following day the diarrhea subsided and by the third day his temperature was normal. However, during a period of sixteen days *Bacterium flexneri* organisms were recovered from his stools on five different occasions. He was then treated with succinylsulfathiazole and all subsequent cultures, twenty-seven in thirty-one days, were negative. (This patient is also included in group 3.)

Group 2 (treated with sulfaguanidine). Ten of the 12 patients who were treated with sulfaguanidine are included in this group, 9 were positive cases and one a probable case. In 7 of 10 patients the temperature returned to normal after three days of therapy, another patient remained febrile for eight days. There was one death in this group, a man who was first given treatment on the sixth day of dysentery. He seemed to be responding favorably, but on the fourth day of treatment his temperature rose to 103 F (rectal) and the following day he died. At autopsy the mucosa of the colon was hyperemic and presented shallow ulcers, cultures of these lesions were negative.
